SUBSTITUTE FOR LEATHER.—A German inventor has devised a new material which is intended as a substitute for leather in many of its uses. This material consists of panels of wood with wire netting between, the whole being glued together under heavy pressure. The sheets thus made are said to be very tough and pliable, and suited for making trunks and other uses that require strength.

SMOKE SCREEN.—Through experiments made by English military authorities it has been found that whenever the atmosphere is laden with smoke or mist the power of an electric light is greatly diminished by crossing the beam of light by that of another at a certain angle. At the point of intersection the illuminated space is practically made a screen. It is proposed to utilize this knowledge, since the electric beam, can thus be made to serve as a screen, back of which tactical operations might be conducted in secret.

FREAKS' JUBILEE.—At the Registrar's office in South Shields, England, on April 26, a girl only 32 inches high was married to Professor Hedley, 6 feet 1 inch high. Humbert, the man without arms, gave the bride away, signing the certificate by holding the pen between his teeth. The bridesmaid was Miss Nina, the American giantess, who weighs 616 pounds. The best man was Captain Dallis, 7 feet 10 inches in height. General Metilone, 29 inches high, was one of the wedding party. All were connected with a travelling circus going through the country.

MODERN MAECENAS.—Francis Wilson is a great book lover, and a special student of Horace. It was Eugene Field's translations of Horace which made Wilson very desirous of meeting the poet, and an intimate friendship is the result. Now the actor is preparing to publish this spring, at his own expense, a little book containing all of Mr. Field's Horace translations. The edition will be limited to fifty copies and the plates will be destroyed. The Latin text will be given on the page opposite the English rendering. The printing will be done in colored inks, and the poems will have vignettes and tail-pieces, the latter drawn by Mr. Field. A life of Horace, written in a vein entirely new to biographies of that ancient poet, will also be contributed by Mr. Field to the volume.

A VALUABLE PUBLICATION.—The May *Arena*, which closes the third volume of this phenomenally brilliant and successful review, contains a remarkably fine picture of the Rev. Minot J. Savage, made from a recent photograph of the great liberal divine. In this issue Mr. Savage appears in a debate with Julian Hawthorne on the subject "Is Spiritualism Worth Investigating?" An admirable picture of Julian Hawthorne and one of Professor Abraham S. Isaacs are also features of the May *Arena*. Probably the four papers which will attract attention outside the Hawthorne-Savage debate in this issue are those by C. Wood Davis on "The Wheat Supply of Europe and America; Professor Emil Blum on "Russia of To-day;" E. P. Powell's critical study of the political life of Thomas Jefferson, and the editor's paper on "Is Socialism Desirable?"

MEN, BIRDS AND KITES.

THE POSSIBILITIES REGARDING THE NAVIGATION OF THE AIR.

We made editorial reference last week to Professor Langley's recent address before the National Academy of Sciences in reference to the possibility of aerial navigation. The subject, with such distinguished advocacy, is attracting extensive attention, for there are many serious thinkers, as Rene Bache declares in one of his entertaining Washington letters, who hope that mankind will some day secure domain in the element of birds, just as it has already done, thanks to the evolution of sub-marine boats and diving gear, in that of fishes. The distinguished scientist referred to expressed confidence that the contrivance of the future for aerial navigation would be on the kite principle. The air possesses elements of buoyancy which have not been recognized hitherto. There is no truth in the popular conception that a body heavier than the atmosphere cannot be suspended in that medium without motion. A kite of sticks and paper is much heavier than the fluid which it displaces, but it is sustained aloft. You can find an example much more striking, however, in the eagle, or the frigate-bird, which, though an animal of considerable weight, remains poised in the sky upon extended pinions motionless for hours together, so that a telescope may be trained on it. Thousands of feet above the earth, it is sustained without movement of a feather, though in a rarefied atmosphere. This is possible because the suspended fowl has a distinctive knowledge of the way in which to utilize the air-currents for its support. When man has learned how this can be done, he will be able to fly. The most advanced investigators in this subject eject the balloon and all other such lifting devices as impracticable; a gas lighter than air can never be safely confined within a receptacle that is not weighty, and the same objection applies to a vacuum. Ballooning to-day is about where it was when it was first invented, and in the nature of things it can never get much further. Aluminum is light, for a metal, but it is several times too heavy to be successfully utilized for such purposes. Pray what has become of those aluminum trains of cars that were to be run through the air from Chicago to New York six months ago, at sixty minutes the trip? There is a school of flying-machine inventors who may be designated as the "flappers," inasmuch as their idea is to sustain their contrivances by the flapping of bird-like wings. But they doubtless forgot that the best flyers among birds do not support themselves by flapping. On the contrary, they only resort to that performance when it is necessary for a start. The eagle, if launching himself from level ground, is obliged to take quite a run first, then flap his wings with a violent muscular effort which he could not keep up for long, and so gain a sufficient altitude to render it possible for him to strike along the plane of an air-current, which holds him up. Floating with librating pinions from one air-current to another, he is lifted, with an occasional broad sweep of his powerful wings, to the upper aerial regions, where he simply floats, opposing to each movement of the suspended ether the gentle force necessary to maintain him in his stationary position. These principles which the eagle applies for purposes of flight are perfectly understood in the theory of mechanics. It is only necessary to adopt them with suitable apparatus in order to give to human beings like powers. True, the bird is lighter in proportion to its size than is man; its bones are hollow and filled with warm air from the lungs. But the difference in this respect is not very material, and it may easily be compensated for by bigger wings. Power to flap them is not what is required, inasmuch as the start can be made from a height; what is wanted is the knowledge which inherited experience, vulgarly termed "instinct," has given the fowl as to how to adapt the angles of the wings to the air-currents. This is precisely what Professor Langley has been experimenting with. What he is attempting is to produce a machine adapted to floatation upon the air-currents, like a kite. You can find a very simple illustration of the principle he is working on in the trick done with playing-cards by the prestidigitator Herrmann, who throws them from the stage into the highest gallery of the biggest theatre in the United States, distributing them one after another among the "gods" of that select circle. How does he do it? Simply by skilfully utilizing the air-currents. The scrap of pasteboard is heavier than the atmosphere, but, judiciously projected, it mounts to a great height and distance with a very little force. It would stay up, too, even if thrown out doors, supposing that it possessed the intelligence necessary to accommodate its surface to the winds. What can be done in this way may be accomplished on a larger scale. Lest this proposition be disputed, it will be sufficient to refer to a flying-machine recently patented in Australia. It weighs altogether nineteen pounds, and its backbone is a long copper cylinder two inches in diameter, filled with compressed air. The compressed air supplies power for a small engine, weighing ten pounds, at the rear end of the cylinder, which works a fan propeller. To the backbone, on either side, is attached a great wing of light material, so that the whole apparatus resembles a big butterfly, with two fans for a tail. This contrivance has been made to fly horizontally 360 feet. Of course, it is only a beginning, but all the same, here is the nearest approach to the practicable flying-machine of the future thus far attained. With the help of a money bequest from a deceased enthusiast, Professor Langley has constructed recently a machine for producing an artificial wind, which he is able to vary in strength all the way from the gentlest zephyr to a storm of sixty miles' velocity. He has been experimenting with this for the purpose of finding out how air-currents act in supporting plane surfaces. One very astonishing discovery that he has made is that, the faster such a plane surface, like a flat plank, is projected edgewise through the air, the less power is required to propel it. Truly, what an astonishing fact is this! On land or in the water, the greater the speed the more the power required to produce it; but in the atmosphere the case is the very reverse, and the faster you go the less expenditure of force is requisite. Thus, a trans-continental line of aerial cars once established, a ticket for the lightning express would only cost a fraction of the price of passage by slow freight, so much less fuel being necessary, not to mention the saving in time and salaries to the company. In like manner Mr. Langley has demonstrated that, the faster the flight, the less is the sustaining power necessary. You can convince yourself very easily that this is so by the same simple experiment that he employed to illustrate the proposition. Take an ordinary shingle and drop it upon the ground. It will fall in a fraction of a second. Then take the same shingle and skim it horizontally through the air. Three or four seconds will perhaps elapse before it touches the ground. The more power you employ in throwing it, supposing that you do it fairly skilfully, the the more slowly it will sink. To a clam-shell the same proposition applies, as every small boy will tell you. And why is this thus? Simply because the shingle, or the clam-shell, well thrown, is upheld by the current of air, as a bird is in flight, and the swifter they go the more easily they are so sustained. This seems very surprising, but let us see if it is not readily accounted for. Did you ever skate over thin ice? If so, you did not stop long in one place, lest it break beneath you. You knew instinctively that the faster you went, and the more your weight was in this manner distributed, the less thickness of ice was needed to support you. If you were able to travel fast enough, the surface of still water would uphold you. Likewise that other fluid called air, if you could only achieve sufficient speed. Now you have the two important principles on which the flying of the future will be based. First, the bird idea must be applied to utilize the currents of air for support in that element. All flying-machines that dispensed with balloons have employed the bird as their model in more or less degree, but they have almost invariably embodied the mistaken notion that a bird relies for flight upon flapping. The models for such contrivances at the patent office here show this sufficiently well. Aeroplanes will represent the bird's wings in the air-ship of the time to come. Such, at all events, is the surmise, and the likelihood seems to be that a steam engine of small dimensions, though powerful, will supply the motive force. Secondly, the motive force required will be at least for the greatest speed, and so proportionately. Professor Langley's notion seems to be this, that such a contrivance as he conceives, elevated in the air, would have no trouble to uphold itself in motion, supposing that its engineer knew how to deflect its supporting wings. In this point there lies an important difficulty, inasmuch as the most intelligent human being has no knowledge whatever of the art which the birds have transmitted to their progeny for thousands and thousands of generations, ever since, as the scientists say, they were first evolved from reptiles in an ancient geological epoch. But the honorable secretary of the Smithsonian Institution is of the opinion that it is possible for human beings, with practice fortified by their superior intelligence, to learn how to use wings in this way, just as small boys acquire the art of walking upon stilts, although such members are altogether artificial. When this art has been acquired, man, hitherto untutored in the science of navigating space, will launch himself abroad and chase the fugacious meteorites on tireless motor-actuated pinions. Seriously, however, there does not seem to be any good reason wherefore such mechanical principles as these should not be successfully applied for navigating the air. At the beginning, the problem of steering and the weight of the motor present themselves, as the two most serious obstacles. Professor Langley has proposed to get over these preliminary difficulties by running the first flying-machine on a wire, such as is used for a certain kind of electric cars. In this case, however, the machine is to fly above, perhaps at a height of two hundred feet, with an attachment to the wire below that runs along the tops of telegraph-like poles. A motor at each end of the line will do the propelling. Thus here will be no engine to carry and the wire will do the steering. How did the birds learn to fly originally? To escape from their carnivorous enemies they developed wings and acquired the art of navigating the air through practice. Now that the true principle of flight has been discovered, it would seem possible to apply it to mechanics so as to secure for man, with sufficient experience, the same power. The muscles of the human being are not strong enough for the purpose, and so he must construct a chariot of some sort to carry him, with a machine on board to do the work. Attention was called only the other day by General Hazen to the tremendous revolution which the introduction of practical air-ships would work in the methods of offence and defence in war. Fortifications, on which it is suggested that Uncle Sam shall expend $20,000,000 as soon as possible, would be of little use against flying-machines that could drop dynamite and other explosives from aloft. Likewise ships of war, however heavily armored, would be at the mercy of hostile aerial navigators. In such a case batteries of a description altogether new would have to be devised for shooting vertically, and the general defending a position on terra-firma would be obliged to assail the winged foe with volleys of bombs directed upwards, as one would shoot ducks on the wing. Should such a state of affairs come to pass, it seems likely that the conflicts of the future between nations will have to be fought out in the air between squadrons of flying men-of-war. About that time, one would imagine, it would be considered that the period had arrived, so long looked for by military thinkers, when there could be no more fighting because it would be too vastly destructive. Having achieved the conquest of the waters, it is natural that

man should likewise desire the mastery of the air, and thus in all ages the human race has been ambitious to fly. The earliest attempt in this direction recorded by tradition is the mythical account Daedalus, who, having constructed the celebrated labyrinth for Minos, king of Crete, was so unfortunate as to offend that monarch, and, being imprisoned, escaped with the aid of wings made of feathers cemented with wax. Another ancient story is of Archytas, of Tarrentum, who constructed a wooden pigeon that had power to fly, "so nicely was it balanced by weight and put in motion by enclosed air." If there is any truth in the account, it seems probable that Archytas was a fakir and worked his bird with a string, as is done on the stage. The ancients, generally speaking, made no attempts in the direction of aeronautics, believing that the power of flight could only appertain to the most powerful gods. Four centuries ago an ingenious gentleman named Lauretus Laurus published a statement to the effect that swans' eggs filled with quicksilver, when exposed to the sun, would ascend in the air; but it is not recorded that the experiment was ever subjected satisfactorily to scientific test. In 1670 a Jesuit, Francis Lana, proposed to make four copper balls each twenty-five feet in diameter and only four one-thousandths of an inch in thickness, from which the air was to be exhausted. To these balls a basket was to be attached, with a mast and sail, and the calculation was that the contrivance would carry 1,200 pounds. Unfortunately, it was discovered that the excessive thinness of the copper spheres would cause them to be broken, when a vacuum was created inside of them, by the pressure of the atmosphere from without. Nevertheless, this suggestion approached more nearly to a practicable idea in aerostatics than any other offered up to the time of the invention of the balloon in 1783 by the brothers Montgolfier. So late as 1775 Joseph Galien, a Dominican friar and professor in philosophy, contended that it would be possible to collect the rarefied air of some lofty mountain-top and enclose it in a huge vessel a mile in diameter, which would carry fifty-four times as much weight as did Noah's ark. Funnily enough, nearly all the early theorists on this subject imagined that the atmosphere merely covered the earth like a shallow ocean, on which the aerial vessels they had in mind were intended to float, like ships in the sea, with their upper portions in the diffuse ether that lay above.

CARE OF CLOTHING.

SOME USEFUL HINTS ABOUT PROTECTION FROM MOTHS.

Among the manifold duties which demand the housekeeper's careful attention during the spring season few are more essential than the proper cleaning and putting away of winter clothing. The first step is to remove every article from closets, wardrobes, trunks or other receptacles where woolen clothing is to be stored. A closet should never have any paper on the walls or carpet on the floor. Every corner and crevice possible to reach should be scalded and then thoroughly wet with spirits of turpentine. Take out every movable shelf and not merely wash, but scald them, and clean every cleat on which they rest. If the walls are broken or cracked fill them with plaster of Paris moistened with cold water. If there are cracks in the floor and between the floor and the baseboard, fill them with putty and then paint the floor. Should the house be infested with the carpet moth, corrosive sublimate should be used. It is very poisonous, but no harm will come from using it in the following manner: Set an old covered stone crock in some safe place out of doors, and fill it with boiling water. Standing far enough away not to inhale any of the fumes as they rise, add one ounce of corrosive sublimate for each gallon of water, and cover closely. When this solution is cold, apply it freely to all the cracks in the floors or shelves and let it dry in. Remove every drawer and scald thoroughly the body of the furniture behind them, and wet every crack and crevice with benzine to which carbolic acid has been added in the proportion of one ounce of the latter to a gallon of the former. Clothes moths have a decided aversion to newspapers, and it is well to cover every shelf with them. Packing boxes or trunks should be lined with them inside, care being taken to paste them in tight. When ready to commence packing choose a sunny day; put every garment out on the clothesline, and after the pockets have been turned inside out and brushed and all whipped free of dust let them hang two or three hours in the sun. If any garment needs sponging do so with water to which spirits of turpentine have been added. Dress skirts will often wrinkle less if folded right side out, and, if possible, kept where it is not necessary to fold them crosswise. Nice dresses should be placed separately in newspapers, with a plentiful sprinkling of whole cloves among the folds, and the edges of the papers pasted so securely together that there is no opening for the entrance of a moth. The sleeves of bodices and all jackets of men's coats should be filled with newspaper, or, at least, a folded piece the size of the sleeve, and a dozen or more of cloves put inside of each pocket. Great care should be taken in folding men's garments not to wrinkle the shoulders of coats or the legs of trousers. Lay a coat out smooth; fold it at the shoulders and under each arm lengthwise; then bring the under arm folds together, by another fold at the centre of the back. Bring each sleeve down on the breast, and do not fold crosswise if possible to avoid it. If each garment is not done up separately in a newspaper after the manner described above for dress skirts, papers should be placed between them. Large bags, either of plain manilla or tar paper can be purchased at paper warerooms. These are of course much easier to use than newspapers, but tar paper is very disagreeable to many people, and garments that have been packed in it retain the odor for a long time. Neither do I consider it as sure a preventive against moths. Carpet moths delight in feasting on birds' wings and the like ornaments in millinery. Be sure they are thoroughly clean, then paste strips of paper over the joining of the bandbox and cover. Securely fasten muff or other pasteboard boxes in which garments are to be put away in the same manner. Fur garments should be put away as early in the season as they are discarded, and before the common moth miller is around. Top garments of seal fur are usually placed with a furrier for safe keeping. Heavy hangings should be spread out and brushed (not whipped) free of dust, and sponged in tepid water to which ox gall has been added in the proportion of one pint of the latter to a gallon of the former. Bed blankets should be carefully washed and dried, and cloves sprinkled plentifully among the folds when put away. Moths prefer garments filled with dust, and for this reason discarded ones should never be hoarded up to afford nests for them.

DOMESTIC DIETETICS.

SPECIALLY PREPARED, FROM PRACTICAL TESTS, FOR THE LADY READERS OF THE "AMERICAN ANALYST."

SEASONABLE FOOD.

May.

MEAT.—Beef, lamb, mutton, ham, kidneys, liver, sausage, veal.

GAME AND POULTRY.—Brant, pigeon, chicken, duck, turkey, goose, snipe.

FISH.—Anchovy, bass, catfish, cod, eels, clams, flounder, halibut, herring, lobsters, mackerel, mussels, perch, porgie, rock-fish, salmon, shad, shrimp, turtle, trout, sturgeon, whiting, weak-fish.

VEGETABLES.—Artichokes, beans, carrots, garlic, lettuce, onions, parsley, parsnips, potatoes, shallots, spinach, turnips, watercress, radish, rhubarb, sea kale.

PRACTICAL RECIPES.

GREEN PEA SOUP.—Put in the soup kettle one pint or one can of peas, one and one-half pints of chicken or any white stock and half an onion, and cook them slowly for about twenty minutes. Remove the onion and mash the peas through a sieve; return to the fire and thicken with four teaspoonfuls of flour rubbed smooth in four teaspoonfuls of butter. Let the soup boil for two or three minutes, then add seasonings of salt and pepper and a cup of cream and a cup of milk. Boil up, pour into the tureen and serve.

LEFT-OVER CHICKEN.—Cut the cold chicken into neat little pieces, removing carefully all bones and gristle; sprinkle them freely with salt and pepper; put a tablespoonful of butter and one of flour into a frying-pan and stir until quite smooth, then add one-half a cup of hot water and boil for a moment, then add sufficient cream or rich milk to make it the consistency of thick cream, put in the pieces of chicken, cook for a few minutes and serve.

SMELTS WITH CHEESE.—Clean thoroughly six good sized smelts, and dry them on a towel. Put into a quart baking-tin a layer of grated bread crumbs, on top of which add a layer of sliced tomatoes (free from skins); cover with a light layer of crumbs and season with salt, pepper and a pat of butter. Now add the fish whole and strew over them a top layer of crumbs, add salt, pepper and a liberal allowance of butter; pour in on one side a small quantity of oyster broth to prevent burning on the bottom, and also to flavor the whole dish; bake twenty minutes.

BAKED TOMATOES AND OKRA.—Slice the okra very thin, and pare and slice the tomatoes; measure your vegetables and see that you have one pint of okra and a good half pint of tomatoes. Stew them together very slowly for a quarter of an hour, then add a tablespoonful of butter, pepper and salt; pour them into a baking dish, sprinkle with crumbs, put some bits of butter over the top and bake for one-half an hour.

BREAKFAST EGGS.—Break six eggs into a sauce pan and beat them up in it; add six tablespoonfuls grated cheese, a tablespoonful and one-half of butter, a little salt and cayenne pepper, stir well while cooking, and serve on a hot platter.

A BACK YARD FANTASY.

THE ELUSIVE PUSS NO LONGER TO BE A TARGET FOR BOOTJACKS.

The following description of a new kind of motor reveals as profound a degree of inventive genius in the writer who concocted the notion as he attempts to attribute to the alleged inventor. It comes professedly as a despatch from Stoughton, Wisconsin, and relates to a new application of cat power, and informs the wondering world that Prof. Richard de Long, the inventor of the new feline motor, is a tall, pale-faced man, with a three-story, bay window forehead overhanging a pair of deep-set, sky-blue eyes, set on each side of a large, thin, hooked nose. He is not a beauty; but he is a genius. His feline motor, which at present is creating such a sensation in scientific circles in Stoughton, is a marvellous machine, unique in appearance and wonderful in operation. It may be described as a curious combination of large and small fly-wheels, great balance-wheels, bright steel rods, and an almost innumerable number of coils of copper wire, all joined to a brightly-polished cylinder of brass, one end of which projects into a wire cage filled with ordinary cats. Its operation is very simple, but surprising in its results. A slight pull on a small nickel-plated lever

starts the machine. Then like lightning from out the end of the cylinder projecting into the cage there shoots a long steel arm and hand, grabbing one of the cats by the nape of the neck and yanking it into the cylinder, where it disappears with a yawl of more than feline terror. In a moment the fly-wheels, the great balance-wheels, and all the complicated machinery begins to move at first slowly, but soon with startling rapidity. At the proper moment, which is indicated by a small clock-like attachment, the operator pulls another lever, when from out of the other end of the cylinder, with hair and tail erect, scintillating eyes, and a caterwaul dislocating to one's spinal column, the cat is projected into a tub of cold water prepared for its reception. This operation, surprising as it may seem, extracts from the cat electricity equivalent to the power represented by ten horses, working for one hour, and this power can be stored in the cylinder until needed. As a cat can be run through the motor every three minutes, and all the accumulating electricity be stored, the power of the machine is practically limitless. The same cat can be used once every ten hours without in the least impairing its health and general usefulness. The Professor is jubilant over the success of his invention. He is satisfied that he has overcome every difficulty, and intends soon to put the machines upon the market. In speaking of the origin of the invention and the probable results of its use, he says: "I have long believed that the cat is nature's Leyden jar, charged with an enormous amount of electricity, but in such a manner as to require a peculiar process to extract it. This process it has been my good fortune to discover. The discovery will be of incalculable benefit to mankind. It will revolutionize the mechanical world and be felt in every department of life. By its means every family, no matter how poor, can have its home brilliantly lighted with electricity at a less cost than to have it poorly lighted with kero sene. By simply running the now practically useless house cat through the machine twice each day a sufficient amount of electricity can be engendered to illuminate brilliantly any medium-sized house. Think how advantageous it would be to large city. Take New York, for example. Carefully compiled statistics show that there are at present within the city limits about 9,998,347 cats. This represents very nearly 20,000,000 continuous horse power, or enough to light the entire city and furnish all the motive power needed to do its work. The feline motor will do away with steam. Ten years from now, I venture to say, there will not be a steam engine in active operation in the United States."

EUROPEAN ENTERTAINMENTS.

THE AMERICAN IDEA COMPARED WITH THAT OF FOREIGN COUNTRIES.

In a recent Paris letter Mrs. John Sherwood says that the American idea is that everbody is hungry. The foreign idea is, that nobody is. The happy medium would seem to be exactly between the two. "Let me give my friend, not too much, yet just enough." The principal thing which the French people do, is to give their guests music at any entertainment. Some one is asked to sing or play, and the guests are expected to be very quiet, and to be enraptured. It is often very stupid, and the guests would rather talk. But the inevitable woman, or male singer, shrieks in a high French soprano, or an equally sharp tenor, most metallic, most disagreeable, or some one inflicts a pianoforte solo, greatest of trials! A french hostess seats her guests in a row in chairs which she designates, and is very much offended if they move. She is unlike an American hostess, who is pleased if her guests move about. If the rooms are full of beautiful bric-a-brac, she (the French hostess) is offended if the guest leave her seat to go and look at the pretty things, but if the guest says, "Would you allow me to go and examine your pretty china," the French hostess seems to be propitiated, and allows her to do so. Therefore a reception, a tea, a call on a French hostess is apt to be very stiff. In Russia, tea is always served. The immortal Samovar is in requisition, and it is very grateful in that cold cliamate. At the parties "champagne *frappe*" flows freely, and delicious cold and hot dishes, fruits, ices and bonbons, are served all the evening. The Russians are very hospitable, and their dinners are now perhaps the best in Europe. Continental people never eat an American breakfast at 9 o'clock, therefore no one in visiting at a country place in Europe, or, indeed, in anybody's house, need appear before 12 o'clock. People take in their rooms a cup of coffee and a roll, which they call *cafe complet*, or they may prefer tea and oatmeal. They have but the morning for reading, literary work, shopping and sight-seeing. At 12 o'clock comes the *dejeuner a la fourchette*, which is a hearty meal, served in courses with red wine, instead of tea. This meal begins with eggs in a variety of forms, a stew of meat, with vegetables, cold meat, stewed pipens, spinach, mutton cutlets, fried potatoes, or trout from the lake, a broiled chicken, cheese, honey, salads, etc., all winding up with a cup of coffee.

A FRENCH DINNER.

After this meal one has the whole day for rest, recreation or work, as they please. Dinner is rarely later than half-past 6 or 7 in summer, on the Continent, as there is a desire to go to the Casino in the evening or to hear music in the park. The dinner in France is always a good one. A first-rate soup, a fish, fresh as a daisy, with a worthy sauce, a filet of beef, one entree, possibly bouchers a la reine, asparagus, green peas, always the inevitable chicken, with a salad, of which the traveller gets—oh! so tired; then ices, fruits, cheese, cakes and coffee, and the wine of the country, for unless on special occasions, French entertainers do not offer champagne, which is quite as expensive in France as it is in America. Americans would do well to copy French frugality. It is not inelegant, it is not inhospitable. It is simply good common sense. English entertaining is superb and faultless at a great house. At an English dinner, from the plainest to the highest, there is etiquette, manner, fine service and everything which there should be. The wit, the courtier, and the beauty, and the poet, aim at appearing well at dinner. "The pleasures of the table," says Savarin, "bring neither enchantment, ecstasy nor transports, but they gain in duration what they lose in intensity. The incline us favorably to all other pleasures, or console us for the loss of them." They console us for our lost illusion. At very few houses, however, even in England among the aristocracy, does one see so elegant a taste, and never anywhere the profusion of flowers in which Americans delight. Indeed, a French gentleman who was dining next to me at an American's table in Paris, told me that it pained him to see money thrown away on flowers. In England one sees very fine linen and beautiful old silver, china and glass; the table lighted with wax candles. Coffee is served immediately after dinner in the drawing-rooms. At a plain country dinner, plum pudding, a sweet omelet or a rich plum tart is served before the game. I imagine this is the remnant of some old fashion, but it prevails in Yorkshire. The dinner, except in a few houses, is rarely as good as the ordinary American dinner except in the matter of fish, which is uniformly very fine. The vegetables are few, and the "sweets" are very fine, generally consisting of a sour tart made of gooseberries. Fine strawberries and pines are, however, very common. All the men are in evening dress and the ladies *decollete* at an English dinner, even in the country places like Melton Mowbray, and as the exposure to cold is getting to be more noticed than formerly, very elegant tea gowns are now allowed. A white or pink satin tea gown, trimmed with sable and made high in the neck, is now often seen at dinner. Servants make the round of the tables in pairs, opening the various courses. People do not talk loud, nor do they gesticulate as Americans do. They eat quietly and speak in low tones. No personal subjects are ever discussed before the servants, of whom there are always a great number. People of very moderate means keep many servants. No hostess ever apologizes or notices any accidents or failures. If the omelette souffle is burned or drops she does not observe it. The servant appears and withdraws it, nor is anyone disturbed thereby. At luncheon, and in some houses, it is still considered proper for the man of the house to carve. At very quiet dinners, the lady helps the soup herself. This is often done on the Continent.

ENGLISH AFTERNOON TEA.

Afternoon tea is an institution in England, and is one of the most agreeable ways of entertaining. Tea is always on tap in England, and whether one joins the table of a famous hostess after the hunt, in a country house, or goes to the more stately afternoon tea of a duchess, it is always the same good tea, with hot toast and muffins, perhaps. In Scotland they give one hot scones and butter, which are very nice, at afternoon tea. The London crushes, the Queen's balls, the receptions at the Foreign Office, are all most enjoyable in these great, splendid houses, which we have not yet copied. A well-bred, well-introduced American lady has the highest position in the English social scale if she knows how to take it and keep it. She should not effuse to much, nor be too generous of titles; still less should she indulge in a too presumptuous boldness, which has of late speedily brought several American women into trouble. The rather perilous admiration of the Prince of Wales for some American beauties has led to this style, but it is advisable that even a very pretty and witty woman should hold herself in check in England. An American should, if she would succeed in English society, have herself presented by her minister. She has then the privilege of attending any subsequent drawing room and is eligible to invitations to court balls, concerts and garden parties. These favorite forms of entertaining are, perhaps, more agreeable to a newcomer than the dinner party, for, unless a person is very agreeable, the first dinner seems stiff. English people are very kind, very hospitable, but they resent anything like a too sudden intimacy. They resent "pushing" more than any people in the world. In no country has intellect, reading, cultivation and knowledge such a success as in England. If a lady, especially, can talk well, she is invited everywhere. But American guests should be worthy of this splendid English hospitality. The English regard a letter of introduction as a sacred institution, and an obligation which can not be disregarded. Invitations to dinner, tickets for any sort of a show, the carriage, the house, all is offered, and a three day's visit at a country house is worth a voyage across the Atlantic. Of course, there are people in England who are discourteous, who patronize, who by their pride of birth make themselves disagreeable. There are well-known English names which are synonyms for snobbery, but we must remember in extenuation, that we have some well-known American families who boast a patrician and hereditary claim to the worst manners in the universe. However, well-born bears are in the minority. It is almost a sure sign of base and ignoble blood to be badly mannered, but all rules have exceptions.

MAKE YOURSELF AT HOME.

If the American visitor treats his English host half as well as his host treats him, he may be assured that the *entente cordiale* will be perfect. An English hostess never gives her guest the idea that she is being "entertained." She throws open the library door, she mentions the lunch and dinner hour, she places horses and carriages at her disposal, she welcomes her on the tennis lawn, she shows her the flowers, but then she lets her alone. The American "high tea" with cold chicken, perhaps a hot dish of roast partridges, hot cakes, biscuits and sweet meats, eggs on toast, etc., has been introduced at 5 o'clock with favor in English

country houses of late. But it is not very much patronized. And while the gentlemen shoots, fishes, and boats, or rides, plays billiards or smokes, the lady should also show a similar tact in retiring to her room, to write letters; she should have the genius and *finesse* to get out of the way, not "hanging round" to be "amused" or entertained. She must not pluck a flower in the ornamental grounds without permission. In each one is a part of the mosaic in the well wrought picture. No one must ride a horse to fast, or too far; or join a party where one is not expected under the trees. Remember, however warmly you have been received, that you are not always wanted. At garden parties a very ample cold lunch is served at the buffet, claret cup, champagne cup, soda water, brandy, and shandy gaff, are placed at convenient places in the grounds. Servants are always ready to serve the guests and to carry off the supply glasses, so there is no confusion in the grounds. Maid servants serve the tea, which should be always hot, and pines, peaches, strawberries and cream, grapes and apricots abound. Campstools or stationary benches are placed about, and a band plays in the distance. The most stately garden parties are given at Lambeth Palace by the Archbishop. One was given by the Queen in her jubilee year, and those at Marlborough House, given by the genial prince and princess are very enjoyable. In fact, England is the land for the garden party, with its turf of velvet softness. The flowering trees, the splendid old oaks, the clipped box avenues, the arcades of blossoming rose vines, the "pleached alleys," and the old-fashioned Dutch gardens, make these parties charming. A garden party near Paris has also its attractions in these fine old houses in the Faubourg St. Germain.

ITALIAN FRUGALITY.

All Italian entertaining is most frugal. A little wine and water, a few cakes, or some very warm orange flower water, or *syrop*, are offered. What would an Italian prince say to an American entertainment, where hot and cold dishes, even a haunch of venison and a *filet de bœuf* with truffles, a cold salmon, dressed with apeca sauce, oysters in every form, salads of every description, boned and truffled turkey and chicken, pates of game, cold partridge and grouse, *patie de foie gras*, hot canvas back ducks, terrapin and game, ices, biscuits, creams, jellies and all the best clarets, champagnes, Johannisberger, and Sauterns, all poured forth as from the cornucopia of plenty. One American supper would feed all Italy for a week. One finds a grand exception to this frugality at the royal palace in Rome. King Humbert and Queen Marguerite are hospitable hosts, and their suppers rival the American. Indeed, they ought to be, for the ancient Romans are famous for suppers since the days of Lucullus. The Germans entertain simply with potato salads, sausages, cheese, beer, wild boar, head cheese, pickles, gooseflesh dried, all sorts of cakes, and if they give you a musicale, the music is good, or they give a very good French dinner with a French chef, but the emperor has issued an edict that there shall be no French printed menus. The French language is one tabooed at Berlin. The Germans are very hospitable, and food, such as it is, is abundant. Hot coffee is handed to a visitor instead of tea, and beer takes the place of all other refreshments. In Spain, one must not expect to be fed, or to be asked to dinner. There is nothing of that kind of entertaining at Madrid or Saville or at Barcelona. The old Moorish idea of the seclusion of women seems to prevail so far as to interrupt any tea givings. The richest man in Madrid has no dining room. He gives five balls a winter and then shuts his doors. In Seville the ladies hold a fair in the open air after Easter, where you are expected to pay your respects to them in a tent, but in their own beautiful houses, with their *patios*, they never receive at breakfast nor dinner, nor do they, it is said, dress until the afternoon, when they drive. Spain is not given to hospitable entertaining. They are simply polite, with offers of opera box and carriage, but they do not ask you to dinner or tea. Indeed, when they eat, or what, is a mystery.

RUST.

IS IT TO BE WATCHED FOR BY THE CHEMIST OR THE ENGINEER?

At a recent meeting of the Association of Engineers in Leeds, England, a lecture on "Rust" was delivered by Professor Smithells. The lecturer said that if they were to do anything on the subject of rust, they must begin by studying the conditions under which rust was formed, getting to know as much as possible about the phenomenon itself. The question was, Was it the chemist or the engineer that was to tackle the problem? The answer in this case, as in so many others, was that the two must work together, they must combine theory and practice. His object would be mainly to take the chemist's attitude, and to explain to them the chemistry of rust, and to hint at one or two ways in which attempts had been made to obviate its formation. Rust, of course, was more or less a general phenomenon. It was not restricted to iron, but was most noticeable in the case of iron because iron was the most abundantly used metal, because the rust of iron formed rapidly, because it assumed a scaly character, because of its color, and because of the fact that rust was a thing that appeared to grow in the case of iron, and it did not grow so rapidly, if at all, in the case of other metals. Most metals, of course, did rust. They knew they could not expose the bright surface of copper or zinc without the surface becoming dim. These metals might, therefore, be said to rust in their respective ways, but the rusting was very slight as compared with iron, which was the most susceptible to rust. Iron rust was found to consist of three elements—iron, oxygen, and hydrogen. That rust did contain water could be shown by the simplest experiments. That rusts were oxides they could easily prove, because they could produce rust by burning metals in oxygen alone. Hence there could be no other element present; but the way that might appeal to them would be

Buffalo Lithia Water, Spring No. 2, in Bright's Disease, Gout, Stone in the Bladder, and Diseases Generally of Uric Acid Diathesis, Etc., Etc.

DR. WM. A. HAMMOND, of Washington, D. C., Surgeon General U. S. Army (retired), Professor of Diseases of the Mind and Nervous System in the University of New York, etc.

"I have for some time made use of the BUFFALO LITHIA WATER in cases of AFFECTIONS of the NERVOUS SYSTEM, complicated with BRIGHT'S DISEASE OF THE KIDNEYS or with a GOUTY DIATHESIS. *The results have been eminently satisfactory.* Lithia has for many years *been a favorite with me in like cases, but the* BUFFALO WATER CERTAINLY ACTS BETTER THAN ANY EXTEMPORANEOUS SOLUTION of THE LITHIA SALTS, and is, moreover, better borne by the stomach. I also often prescribe it in those cases of CEREBRAL HYPERÆMIA resulting from OVER MENTAL WORK—in which the condition called NERVOUS DYSPEPSIA exists—*and generally with* MARKED BENEFIT."

DR. WM. B. TOWLES, Professor of Anatomy and Materia Medica, in the Medical Department of the University of Virginia.

"BUFFALO LITHIA SPRINGS, No. 2, belongs to the ALKALINE or, *perhaps, to the* ALKALINE SALINE Class, *for it has proved far more efficacious in many diseased conditions than any of the simple* ALKALINE waters.

"*I feel no hesitancy whatever in saying that in* GOUT, RHEUMATIC GOUT, RHEUMATISM, STONE *in the* BLADDER, and in all diseases of URIC ACID DIATHESIS, *I know of no remedy at all comparable to it.*

"*Its effects are marked in causing a disappearance of* ALBUMEN *from the urine. In a* single case of BRIGHT'S DISEASE *of the* KIDNEYS, I witnessed *decided beneficial results from its use, and from its action in this case I should have great confidence in it as a remedy in certain stages of this disease.* In DYSPEPSIA, especially that form of it in which there *is an excessive production of* ACID *during the process of nutrition*, in some of the PECULIAR AFFECTIONS *of* WOMEN, notably in SUPPRESSION of the MENSES, and in CHRONIC MALARIAL POISONING, etc., I have found it highly efficacious."

DR. G. HALSTEAD BOYLAND, late Professor of Surgery, Baltimore Medical College, late Surgeon French Army (Decorated), Member Baltimore Academy of Medicine, Member of American Medical Association.

"In BRIGHT'S DISEASE of the KIDNEYS, ACUTE or CHRONIC, BUFFALO LITHIA WATER, Spring No. 2, is, in my experience, *without a rival*, whether in the PARENCHYMATOUS form or INTERSTITIAL NEPHRITIS. In cases in which the ALBUMEN in the URINE reached as high as 50 per cent., I have known it under a course of this water gradually diminish and finally disappear, at the same time other alarming symptoms were relieved and the sufferers restored to health.

"In STONE in the BLADDER of the RED LITHIC ACID and the WHITE PHOSPHATIC DEPOSIT, the SOLVENT power of this water is *unmistakable.*"

Water in cases of one dozen half gallon bottles, $5.00 f. o. b. here.

THOS. F. COODE, Proprietor, BUFFALO LITHIA SPRINGS, VA.

by getting the metal back again from the rust, and the oxygen as well. The lecturer demonstrated this by experiments with iron rust. The experiment he had done, he remarked, was a very suggestive one, because in getting the iron back from the rust in that particular operation he had done what had to be done so often in the process of soldering. They knew that before they could unite two pieces of metal by solder they must use a flux. The reason was that the two metals might be covered with a thin film of rust, and the solder would not adhere to these two unclean surfaces. What was the cause of iron rust? They all knew that rusting was favored by the presence of the air, and by the presence of moisture, but they wanted to know which of these two was the active agent, whether both were necessary, and whether anything else took part in the process. They wanted to know why rusting went on so rapidly and at different points, and how it was affected by the different composition and qualities of the metal, and by impurities in the metal, in the air, or in the water. Professor Smithells then showed some specimens of iron in jars, which he had been preparing for some time. One was a piece of iron in dry oxygen, and he explained that that would not cause the iron to rust. Next he showed a piece of iron which had been sealed up in water for some days, remarking that it was found that when they excluded air and other gases from the water no action took place, and a second conclusion was that water alone would not affect iron. The next question was—would air and water together affect iron? That experiment had been tried, and it had been shown that, wherever action had taken place at all, the action had been exceedingly insignificant, and the question arose—what was it that was absent and that caused the rust? The one ingredient which was present in one of the jars, and was not present in the cases he had shown, was carbonic acid gas. Carbonic acid gas existed in the atmosphere to a small extent, and it was this gas in the air that was all important in the operation of rusting. Pure air, pure water, pure carbonic acid, would not act singly upon iron; pure water and pure air would not act together upon iron, carbonic acid and air would not act upon iron, but when they had carbonic acid, water, and air together, they got rust. It was carbonic acid that really set up the rust action, and when it was formed, the carbonic acid was liberated and attacked the layers beneath. That was why rust had got the property of traveling inward. How could they prevent this action of rusting? There were many things which had been tried. They might paint the iron, and if they observed certain precautions, they might have an effective method.

One precaution was that the metal must be perfectly clean. A spot of rust embedded below a coat of paint would often break out of itself. Then there was the method of covering the iron with oils and tarry matters. There was also the process of galvanizing iron, the process of enameling, which was very useful for small articles, but the enamel was apt to chip off, and there was the Bower-Bariff process, which was worked at Keighley, and which was an admirable process. Alluding to boilers, he said that by putting soda into them not only did they correct acidity of the water, but they introduced something which would absorb the carbonic acid gas, and prevent it acting in a rusting capacity.

Girls.

BY HELEN EKIN STARRETT, IN *The Forum.*

"Thousands who are now in shops and other organized industries would really prefer work in homes, if only the heavy, grimy, malodorous, *clothes-destroying* work of cooking and laundering were not required and expected of them."

Well—if this is true there's a good time coming for girls and the mistress too; for women (by millions) are coming to know, that *Pearline* saves the clothes on your back as well as the clothes in the wash; the paint on your walls—the sheen of silver—the lustre of glass and reduces the labor—drudgery—health breaking—temper and comfort wearing work of washing and cleaning to almost nothing.

Besides—the girl—the mistress—or both—are better satisfied with the results. It cleanses—restores original colors—but hurts nothing, not even delicate skin—luxurious for bathing—be among the bright ones and use *Pearline.*

Beware Peddlers and some unscrupulous grocers will tell you, "this is as good as" or "the same as Pearline." IT'S FALSE—Pearline is never peddled, and if your grocer sends you something in place of Pearline, do the honest thing—*send it back.* 192 JAMES PYLE, New York.

THE SECRET OF BEAUTY.

An ominous feature of modern society is the extensive use of dangerous drugs and chemicals for the purpose of augmenting personal beauty. The practice has been studied thoroughly by more than a hundred Boards of Health in the United States, and in almost every instance has been denounced in the bitterest terms. Objectionable goods are sold everywhere in large quantities and in many cases have brought fortunes to their manufacturers. The desire to be pleasing in appearance, upon which this nefarious traffic is based is natural and praiseworthy. It expresses unconsciously a great physiological principle, that beauty means health and ugliness disease. A man or woman in perfect physical condition is always invariably delightful to look upon. It is the same physiologic principle which teaches that to acquire beauty, we must first obtain health, not mere freedom from positive illness, but real, complete health in every regard. This is acquired more easily than is commonly supposed, and consists in expelling from the organization the humors which underlie and cause all disease, and which change beauty into that which is repugnant to the eye. Humors or impurities affect the system in many ways. They are deposited by the blood-vessels in the tissues of the skin and by degrees change the rose-pink hue to a gray or brown. They settle in and around the minute orifices and cause the pores to enlarge, and the cuticle about their ends to roughen up. They change the fine oil of the epidermis into a solid whitish grease, and by inducing local inflammation produce pimples, cat-boils, pustules, boils and even carbuncles and ulcers. They act in an inflammatory way upon the inactive tissues and by degrees the nose turns red, the surface around the nostrils becomes sore and the chin suffers from an eruption. The orbit of the eye darkens and becomes discolored and the eye itself loses its color and brilliancy. The eyelids swell and produce styes and the skin of the forehead grows thick and harsh. All of this results from the slow action of the impurities which accumulate in the blood. It is unfortunately so common as to escape remark except it be, "that person is out of sorts. He needs a dose of medicine." What is really needed is a blood-purifier. Something that will attack the humors, break them

Hay, choice to fancy, perpetual pressed bales	14.00 to 15.00
Hay, fair to good	13.00 to 14.00
Hay, poor to ordinary	11.00 to 12.00
Hay, Clover and Clover mixed	10.00 to 12.00
Hay, swale	8.50 to 9.00
Straw, Rye, good to prime	17.50 to 18.00
Straw, Oat	8.00 to

BOSTON, May 23, 1891.

Receipts for the week are 197 cars of Hay and 8 cars of Straw; corresponding week last year, 215 cars of Hay and 21 cars of Straw. There is little change in the general condition of the market from those noted a week ago. The receipts have continued small and the market is well cleaned up and firm; some strictly fancy cars of hay in large bales, selling as high as $16. We still believe it worth a special effort to get shipments in now while the market is strong and before the usual heavy receipts in June and July. Rye straw is steady with some choice cars selling at $18.50.

down and drive them out of the system. This is best done by Ayer's Sarsaparilla, a superb scientific combination of vegetable remedials, the best preparation known to modern medicine for accomplishing the work desired. It purifies the blood and at the same time tones up all the vital organs. As the humors disappear, the skin becomes thin, soft and smooth, the eyes resume their brightness, the eruptions and other facial disfigurements vanish, and in a short time the face that before was plain or disagreeable, becomes healthy and attractive. There is only one secret of beauty and that is perfect health, and the most effective way to secure perfect health is by using Ayer's Sarsaparilla.

BUSINESS NOTES.

HORSFORD'S ACID PHOSPHATE.

A nerve-food and tonic. The most effective yet discovered. Dr. J. E. Lockridge, Indianapolis, Ind., says: "From my experience, I would say that as a nerve-restorer in exhaustion from any cause, and as a sleep inducer, it is of the greatest value."

Tabasco Pepper Sauce

OR LIQUID PEPPER.

Is simply the Pulp of the Ripe Pepper Extracted by Pressure.

The seed of this Pepper was obtained from Central America, and by careful cultivation in Louisiana for many years has been so improved in strength, flavor and aroma, as to have become a new variety of Red Pepper, superior to all others. The pulp is so handled as to retain all the flavor, strength, aroma and color of the ripe fruit, and to keep unimpaired in any climate. It excites the appetite, promotes digestion, and is pronounced, by connoisseurs, to be the finest condiment in the world. For medicinal purposes it recommends itself by its purity, strength and diffusible form.

GRAND PREMIUM OFFER!

A SET OF THE

WORKS OF CHARLES DICKENS,

In Twelve Large Volumes,

Which we Offer with a Year's Subscription to this Paper for a Trifle More than Our Regular Subscription Price.

CHARLES DICKENS.

Wishing to largely increase the circulation of this paper during the next six months, we have made arrangements with a New York publishing house whereby we are enabled to offer as a premium to our subscribers a **Set of the Works of Charles Dickens, in Twelve Large and Handsome Volumes,** with a year's subscription to this paper, for a trifle more than our regular subscription price. Our great offer to subscribers eclipses any ever heretofore made. Charles Dickens was the greatest novelist who ever lived. No author before or since his time has won the fame that he achieved, and his works are even more popular to-day than during his lifetime. They abound in wit, humor, pathos, masterly delineation of character, vivid descriptions of places and incidents, thrilling and skillfully wrought plots. Each book is intensely interesting. No home should be without a set of these great and remarkable works. Not to have read them is to be far behind the age in which we live. The set of Dickens' works which we offer as a premium to our subscribers is handsomely printed from entirely new plates, with new type. The twelve volumes contain the following world-famous works, each one of which is published *complete, unchanged, and absolutely unabridged:*

DAVID COPPERFIELD,
MARTIN CHUZZLEWIT,
NICHOLAS NICKELBY,
DOMBEY AND SON,
BLEAK HOUSE,
LITTLE DORRIT,
OUR MUTUAL FRIEND,
PICKWICK PAPERS,
BARNABY RUDGE AND CHRISTMAS STORIES,
OLIVER TWIST AND GREAT EXPECTATIONS,
THE OLD CURIOSITY SHOP AND THE UNCOMMERCIAL TRAVELER,
A TALE OF TWO CITIES, HARD TIMES AND THE MYSTERY OF EDWIN DROOD.

The above are without question the most famous novels that were ever written. For a quarter of a century they have been celebrated in every nook and corner of the civilized world. Yet there are thousands of homes in America not yet supplied with a set of Dickens, the usual high cost of the books preventing people in moderate circumstances from enjoying this luxury. But now, owing to the use of modern improved printing, folding and stitching machinery, the extremely low price of white paper, and the great competition in the book trade, we are enabled to offer to our subscribers and readers a set of Dickens' works at a price which all can afford to pay. Every home in the land may now be supplied with a set of the great author's works.

GLENN'S SULPHUR SOAP.

Glenn's Sulphur Soap is the **Original** and **Best** combination of its kind, and the one now generally in use. For sale by **All Druggists.**

BEWARE OF COUNTERFEITS.

Wholesale Depot,

C. N. CRITTENTON,
115 FULTON STREET,
NEW YORK.

Be progressive and keep abreast of the times. Avoid dyspepsia by using **Lard Compound** and **Cottolene,** a substitute for lard.

The highest medical authorities pronounce them healthful; and expert cooks commend them.

Our **Clairette** brand of cotton oil soap is the purest and best laundry soap in the market; as pleasant to the hands as genuine castile.

N. K. FAIRBANK & CO.,
CHICAGO AND ST. LOUIS.

OUR GREAT OFFER
TO SUBSCRIBERS
TO THE
AMERICAN ANALYST.

We will send the **ENTIRE SET OF DICKENS' WORKS,** *in* **TWELVE VOLUMES,** *as here described, all postage prepaid by ourselves, also* **THE AMERICAN ANALYST** *for* **ONE YEAR,** *upon receipt of* **$1.50,** *which is only* **50** *cents more than the regular subscription price of this paper.* Our readers, therefore, practically get a set of Dickens' works in twelve volumes for only **50** cents. This is the grandest premium ever offered. Up to this time a set of Dickens' works has usually been $10.00 or more. Tell all your friends that they can get a set of Dickens' works in twelve volumes, with a year's subscription to **THE AMERICAN ANALYST** for only **$1.50.** Subscribe now and get this great premium. If your subscription has not yet expired, it will make no difference, for it will be extended one year from date of expiration. We will also give a set of Dickens', as above, free and post-paid, to any one sending us a club of three yearly subscribers.

WOMEN PRINTERS.

A statement appeared in the *Sun* some time ago to the effect that women are physically unfit for the trade of type-setting, and moreover that since the introduction of the type-writer and the opening of other more agreeable and suitable lines of employment the female labor market has been relieved of the greater part of the women who formerly wished to be printers. It is estimated that there are not over three hundred women printers in New York, their work being principally in large book-publishing establishments where the hours are easy and there is no rush. A few others are employed in morning newspaper offices, working in the afternoons at distributing the type. We have heard it stated that these last mentioned operatives are not over twenty-five in number in the whole city. Their employment is described as pleasant and lucrative. They are employed during the day, at the same rate paid for night work, to distribute type for compositors who thus reduce their working hours. The "lady distributor" is comparatively a recent innovation. Her earnings depend upon the amount of work she receives, but will average about fifty cents for every hour employed. Some women thus earn twenty dollars per week, from about 10 A. M., until 5 P. M. These positions, are in the main greatly prized and eagerly sought after, notwithstanding that the printing trade, according to the *Sun* writer above mentioned is "too wearisome, too unhealthy and in other ways unsuited to women." Our earnest little contemporary, *The Nightingale*, whose song is always tuned in behalf of women's progress, takes up the editorial cudgel in support of the female printer. It concedes with some slight tinge of sarcasm, that the business of type setting as practiced by men is unquestionably unhealthful. "This is due partly it is said to the fact that lead and antimony enter into the composition of type metal. Lead poisoning is however, not at all common, although we do not deny that such cases may occur. The diseases from which compositors suffer would appear to be consumption or phthisis, and the effect of undue indulgence in alcohol and tobacco." To this must be added the injurious effect of working in overcrowded and poorly ventilated rooms, as is the case with the majority of composing rooms in this city." "But," says the *Nightingale*, "the *Sun* correspondent speaks of the unsuitability of this business for women, referring we suppose to the business as a whole. In the first place you cannot set type without blackening your hands, but neither can you black a stove, sweep a room or wash dishes without soiling your hands; and while a little kerosene oil added to the wash-water and a good nail brush will quickly remove printer's ink, the same cannot be said of the stains from some other trades. But the business requires, further, the lifting and moving of a galley-full of type and this, it is said women are not physically able to do. In answer it can be stated that a galley-full of type is not heavier than a scuttle full of coal or even a good sized pail-full of water, and yet no one objects to the employment of women for the lifting and carrying of these loads. In the second place any woman ought to be able to lift a galley of type. If she is not able to this she is not only unfit for this business, but also for a good many other lines of work open to women. It may be asked how a woman can lift and carry such burdens without injury. The woman who does not wear corsets, who has her skirts attached to a skeleton waist, and who has in addition the bands of these skirts reasonably loose can lift with impunity any thing which her hands and arms can carry. She will be made stronger instead of weaker by the exercise. It is lifting with a compressed waist which injures women. The reason is not difficult to understand." That is earnestly stated, and challenges approval, if it does not wholly enforce conviction. It is evident, however, that the fitness of women for working in printing offices, will not be established until the experiment is tried in an office employing none but female operatives. The two sexes apparently cannot work together without mutual disadvantage. For, the writer says, a little further on, "Women who work in the large offices with men are made the recipients of an amiable gallantry, they have their galleys moved for them and their measures set, and in some cases their proofs corrected. They are assured that these things are not a woman's work ; and the girls, flattered and assisted, have believed it. So it has come about that expert women compositors do not care to work in a woman's office where they must do these things for themselves just as the men do. They miss the gallantry and the help. They like their dependent position and do not want things any different." This sentimental phase of the question weakens our contemporary's position materially, and we dismiss the subject with the impression that in the present discussion at least, the men have the strongest argument on their side, as they likewise have the strongest muscles and evidently the strongest control of their emotional natures.

CONDENSED CREAM AGAIN.

In its April issue our young and enterprising contemporary, the *National Standard*, resorts to the following special plea on behalf of one of its advertisers :

By referring to the editorial page of this paper it will be noted that "food products only will be advertised, and only such articles of food as are well known to be of the highest grade and purest quality. We have also stated, editorially, in a recent number of this paper, that should any manufacturer obtain a place in our advertising columns through false representations, that we would treat such a party as we would any other imposter. Our attention was recently called to an article in one of our contemporaries, which reflected somewhat upon the character and quality of the condensed milk known as the Highland Brand of Evaporated Cream, manufactured by the Helvetia Milk Condensing Co., at Highland, Illinois. Whilst perfectly well satisfied at the start that this milk is a pure and wholesome article, in order to make assurances doubly sure, we purchased a tin of this milk in open market and sent it to our chemist for analysis. As the chemist to whom it was sent stands at the head of his profession, and as he did not know whose milk it was that was sent to him for analysis, nor did the manufacturer know the chemist in the matter, the result of this analysis cannot but be not only an intelligent but honest one. The result of this analysis shows beyond peradventure or doubt that the condensed milk known as the Highland Brand of Evaporated Cream is as pure and wholesome an article as is on the market. It contains no preservatives whatever, which means that there are no ingredients in its composition that is in the least ways injurious to health. On the contrary, it is a milk of the purest quality, and as such it is worthy of the consideration and attention of all those in search of a pure and wholesome condensed milk, whether it be for infants, invalids, or for those in perfect health. There are a great many people who cannot use the sweetened milk, and to these Helvetia Milk can be

unhesitatingly recommended. It is the only condensed milk, so far as we have ever come across, that can be used in cooking oysters. This alone is specially worthy of note. It is also a delightful beverage, easily prepared and as easily digested by the weakest stomach.

The article referred to in the foregoing quotation was published in the AMERICAN ANALYST of March 26, and for reasons that will be obvious is herewith reproduced in full:

There is a brand of something, that looks like condensed milk, sold in cans, which the manufacturers claim is condensed cream. To condense cream the same as milk is condensed is an utter impossibility, because of the excessive amount of fat contained in cream. Cow's milk contains, on an average, 3.86 per cent. of fat. The cream of cow's milk contains 35 per cent. Fresh condensed milk without sugar contains, on an average, about 15 per cent. of fat, while that preserved with sugar contains between 11 and 12 per cent. of fat. What we call fresh condensed milk, without the addition of sugar, is the kind of milk sold from wagons in the large cities, and will not keep any longer than ordinary uncondensed milk. If this kind of fresh condensed milk is put in cans and exposed to a high temperature, it is sterilized, and will keep until the can is opened and exposed to the air, when its keeping qualities are again reduced to those of ordinary milk. But in the sterilizing process the fat globules in the milk are broken up, and thus the entire character of the milk is destroyed. While fresh condensed milk is certainly superior to and richer than the best ordinary milk for use in coffee, it is only a substitute for cream and not cream. It is therefore clear that any manufacturer who puts up fresh condensed milk exposes it to a process which takes from it all the characteristics of milk and sells it for cream, and at the price cream is selling to the innocent purchaser a different article from what it is, and perpetrates a gross fraud. We have been informed that the Pullman and Wagner palace dining cars use this stuff as condensed cream. They may learn from this article what its true nature is, and thus be enabled to save themselves from paying an inequitable price for an inferior article and imposing on their patrons.

Our contemporary, it will be noticed, admits, though unintentionally, of course, that the criticism we made upon the compound under discussion was correct and just, by calling the article which is advertised and sold as condensed "cream," condensed "milk." The chemist to whom the tin of "milk" was sent, naturally found it to be condensed, unsugared milk, but evidently did not certify that it was condensed cream. He found it pure and wholesome. We did not say that it was adulterated or unwholesome. He does not say that our assertion that by the sterilizing process to which this so-called condensed cream had been subjected, the fat globules were broken up and the entire character of the milk destroyed was not so found by him. Practically the chemist employed by our contemporary found the milk just what we said it was, and had he been asked whether our article was correct he would undoubtedly have said it was. In these circumstances, we would suggest that the *National Standard*, in order to be consistent, should change its head-lines and lower its standard.

THE COPYRIGHT LAW.

The effect upon the cost of books, which is the popular and practical side of the question, to be looked for from the new Copyright law is ably discussed by a writer in the *Forum* for this month. Summed up in brief his argument is that it is to be expected that under the new law our first editions will generally cost more than now, but will be enough better made to be worth the difference, and that our own authors will sell more of them, and at a larger royalty. But it is also to be expected that in the case of books that "the people want," these first editions will be succeeded by cheaper ones—just as cheap as the people will provide a wide market for. These will be in addition to the books whose first editions were issued long ago, but for which a wide demand is still possible; for them, publishers will be encouraged to cultivate this demand by cheap durable editions, when they have no longer to contend against the opposition of the poor material on which our people have been principally "educated" (outside of school) for half a generation. Averaging all sorts of books the gain will be very great, for it is not so important to have the new book cheap, even if that did not involve underpaying the author, as it is to have cheap the book that has stood the test of time, or at least that of contemporary opinion.

FISH FARMS.

PROSPECTIVE CULTURE OF THE LAKES AND OCEANS.

Within a century from the present date the waters of this country will supply as much food as the land produces. So the authorities in the Fish Commission and geological survey assert. By that time water farms will have become as plentiful as land farms, and the aqueous acres will be cultivated with as much attention as the terrestrial. Water-farming is, in fact, to be the great industry of the future. It is far more profitable, even now, for a given area than the tilling of the most fertile soil. A fruitful acre of earth will support one young bullock, increasing the weight of the beast five hundred pounds in a twelvemonth. One acre of water, properly located, will produce 10,000 pounds of oyster meat, shells and juice not included, in the some length of time. Oysters are, weight for weight, very nearly equal to beef for making flesh and blood. By artificial propagation, as it is now beginning to be carried on, the entire bottom surface of all streams near the sea, and estuaries also, can be made to yield crops in this proportion. But great as will be the business of raising oysters on our coasts a century from now, it will bear but small comparison with the cultivation of fish. This will be carried on in three branches. The most important will be their propagation for market in the waters of the interior, which will afford opportunities hitherto undreamed of for economic fish-farming. It is not generally realized that there are in this country literally millions upon millions of lakes available for this purpose, in size all the way from mere ponds to the great inland seas of fresh water. In Illinois alone there are tens of thousands of lakes, and hundreds of thousands more can be readily created. There are in that State hundreds of thousands of extinct lakes which can easily be transformed into sheets of water by the simplest means All the enormous "Lake Plain," as it is known to geologists, comprising Wisconsin, Minnesota and Michigan, north of the Ohio River, is dotted with countless sheets of water, conditions being abundant for creating a million more by such inexpensive arifices as the damming of streams. By damming at intervals, every creek and rivulet can be made to form artificial lakes. Everywhere in the United States it is pretty much the same, and every acre of this water can be made to produce several times as much food as can be obtained from the most fertile acre of land. Even the vast arid region—the "Great Desert" of the West—is speckled all over with multitudes of extinct lakes, which can be filled once more and made to teem again with fish life, as they once did. In the marshes, where once these dead ponds were, countless shells and fish-fossils are found to-day. From such sources were obtained the remains of mastodons preserved in the museums, the mighty beast having got mired when they went for water and so perished, leaving their bones behind them to excite the wonder of a later age. When the irrigation of the arid belt has become an accomplished fact, the water stored in reservoirs will produce as much value in the shape of fishes as from the land in the form of vegetables. All these millions of water farms, as they are some day destined to be, will be planted with fishes native to the Mississippi Valley—such as the crappie, black bass, rock bass and pickerel—as well as with land-locked salmon, carp and other suitable species, palatable and quickly multiplying. This Mississippi Valley itself, by the way, with its multitudinous bayous, will afford extensive and most profitable areas for the propagation of scaly food. In short, all the fresh water is at hand that can possibly be wanted for the growing of fish in any quantity that may be desired. One principle at the bottom of the fact that water farming makes bigger gains than land farming is that, whereas a pound of beef must carry its own weight, as it were, the animal wasting most of what it eats in the muscular effort of walking about, the fish is suspended without effort in its native element, having merely to waggle its fins occasionally in order to achieve what locomotion is necessary, so that nearly all of its food goes to support and increase the bulk of its body, at so much per sixteen ounces, market price. The second great branch of the water-farming industry of the future will be the cultivation of the coastal waters of the Atlantic and Pacific oceans, as well as the Gulf of Mexico. It is as easy to stock those waters as to do the like for the ponds and lakes, and operations for propagating purposes can be carried on with equal certainty of success. The migrations of the cod are as limited and well-defined as those of the shad. Cod do not go far from shore, merely retreating into deep water in summer and coming back to the spawning grounds to breed in winter. The area of their range is always a definite one, and propagation can be carried on inside of that area with perfect confidence in sure results. Within the last half-dozen years the Fish Commission has remade the great cod-fishery off the New England coast. During the month of January last it took for hatching two hundred and fifty million cod eggs. Out of this number about one-half will be safely hatched and will grow to three inches in length, when they will be carried in tanks upon steam launches to the fishing grounds and dumped overboard to shift for themselves. It is estimated, well within the mark, that of these 125,000,000, fifty millions will escape the maws of bigger fishes and other perils of infancy and grow to be adults. Suppose that these fifty millions averages ten pounds apiece, though they ought to average twenty pounds, and cod often reach eighty pounds, and that they are worth only three cents a pound, that makes fifteen millions of dollars' worth of cod created by one season's hatching, with small expenditure and comparatively little labor. By a not very costly expansion of the work the schools of cod on the shores of New England could undoubtedly be multiplied in numbers by ten. The only limit to such multiplication is the amount of food available in the sea for the fish, and there is plenty of that and to spare. Each female cod lays hundreds of thousands of eggs at a spawn, but owing to natural causes, nearly all of them are lost. They float on the surface of the water and furnish food for every fish that swims. Depending as they do for being rendered fertile upon accidental contact with the floating milt of the male, most of them remain unimpregnated, and every breaker casts upon the rocky beaches by a northeast storm destroys them by myriads. But by the artificial method, the eggs and milt being stirred together in a pan of water, nearly all are hatched, and the little fishes are taken care of until they can look out fairly well for their own preservation. Speaking of the cod fisheries, Professor Huxley says—"The fishing grounds are much more prolific of food than the same extent of richest land. Once in a year an acre of good land, carefully tilled, produces a ton of corn, or two or three hundredweights of meat or cheese. The same area at the bottom of the sea in the best fishing-grounds yields a greater weight of food to the persevering fishermen every week in the year. In recent discussion of the question of reciprocity in trade between this country and the South American republics, no one seems to have thought about the cod, which in those countries is considered the greatest of all delicacies. When the treaties are signed this government cannot do better than appropriate a big sum of money for increasing the product of cod to its maximum, which could be accomplished within a few years by the Fish Commission. As quickly as these southern markets are opened by the removal of duties, there will be an

enormous new demand by a whole continent that is actually starving for codfish, hitherto purchasable for nothing under sixty cents a pound, and therefore forbiden to all save the well-to-do. What is being done for the cod is to be done also very soon for the mackerel, which is becoming very scarce and dear, the Spanish mackerel, the haddock and the halibut. Most difficulty is anticipated in propagating the last-named fish, for the reason that it lives in great depths, and, on account of the difference in pressure that it experiences when drawn to the surface, soon dies, so that it cannot be got to the shore alive for taking its spawn and milt. But this will probably be gotten over by taking the eggs and fertilizing them far out at sea, where the halibut are captured. On the Pacific coast lobsters are being planted by millions, in the shape of little fellows a couple of inches long, and they are thriving so well, though unknown on those shores hitherto, that as soon as they have had time for multiplying, they are likely to supply the whole country, including New England. In fact, it looks as if Bostonians of the future would have to draw upon Portland, Ore., for their lobsters. Conditions on the west shore of the country, it seems, are more favorable to lobster propagation than those of the east coast, owing chiefly to the more even temperature of the water. Though much has already been done for the shad, which has been multiplied many times over in eastern waters by artificial hatching and made one of the commonist of fishes in the streams of the Pacific coast, where until recently it was unknown, only a beginning has been made of what is destined to be accomplished in its propagation. One advantage which it possesses, in common with some other fishes, is that it feeds on the ocean bottoms, where the amount of provender is unlimited, and at spawning time fetches into the rivers for the use of man the crops of those bottoms, otherwise unaccessible, in the shape of toothsome flesh. The seas will support any number of shad, and in order to crowd the streams with them every year, it is merely necessary to hatch enough of the eggs and put the fry into the water. It is the same way with salmon. This propagating of such river-fishes is in fact the third branch of the water-farming of the future. New and improved methods and processes for multiplying the fish supply of every kind are constantly being discovered, with results that are really wonderful Thus far nothing has been said of the feeding of fish artificially, which, together with a copious water supply, may be said to constitute what is equivalent to so-called "intensive" farming on land. Given a flow of one hundred gallons of water per minute, and plenty of liver and scraps thrown in, and you can raise one thousand pounds of trout in a pond ten feet deep, ten feet long, and ten feet broad, replacing them with small ones as rapidly as they reach remarkable size. It can be done very profitably, too. The time is looked forward to, and it is not far away, when every farmer will look upon an acre of water as he does upon an acre of land, expecting so much yearly yield from it, whether it is pond, lake, river, or estuary.

ARYAN ART.

WHAT THE WORLD OWES TO THE ARTS OF PERSIA.

Mr. S. G. W. Benjamin, formerly United States Minister to the Court of Persia, says that we talk of what we owe to the arts of Greece and Rome, and of what they owed to Egypt. But how often do we ask or do they realize what they and we owe to the art-thought of Persia? The Persians, who call their country Irvan or Erau, from Arcia, whence our word Aryan, are first brought prominently before us in authentic history when Cyrus or Kur invaded Asia Minor, and came in contact with the Greeks while attacking their colonies on the eastern shores of the Ægean. But they were already an old people. Cyrus was merely one representative of a race abounding in heroes, a race which had for ages been working westward from Central Asia, and had at last reached a position where the forces developed demanded an outlet in foreign conquest. During several centuries of this prehistoric period Persia was alternately under the dominion of Babylonia or Chaldæa, and Assyria. That interval of subjection is one of the most interesting and valuable of any known in the history of the fine arts. The Greek writers tell us little or nothing of its wonderful results. But if we turn to the remains of Persian art we meet records which enable us to trace its development perhaps to its very beginning, and which also indicate one of the most important features of its influence to the present time. The Akkadians and Chaldæans of Babylonia, and the Assyrians, as we now know, had distinct art schools of their own. Before Cyrus's time the Persian æsthetic genius had been awakened by contact with the arts of those peoples, and when the Persians asserted their independence, presumably under Feridoon, a Persian art school sprang into existence. Though suggested by the art of their former masters, it yet bears the unmistakable stamp of a great intellectual race—an art perhaps the most remarkable yet seen in Asia for its power, but especially for its imperishable vitality. The Babylonian Ninevite arts came to a definite close nearly twenty-six hundred years ago. But Persia is still practicing the arts, and her types and ideas are still potent in directing the expression of thought in material forms of beauty in Western Asia and in Europe. The stately columns of Persepolis present, as far as we can now discern, a strictly original style, with their slender fluted shafts peculiar to Persian architecture up to the present time, and reproduced with the same general *motif* wherever we find Saracenic art or suggestions borrowed from it, whether at Ispahan, Constantinople, Cairo, Grenada, or in the Christian styles of Portugal and Spain. The general form of the bull-headed capital, the bull-head being omitted but the spreading outline preserved, is still followed in Persia, and undoubtedly had its influence on the capital of the Greek, Byzantine and Gothic orders. The recent explorations at Susa, the ancient Shushan, in south-western Persia, where the remains of three different palaces are superimposed, one above the other, representing, as it were, three stratified periods, offer conclusive evidence of the influence of the Babylonian and Assyrian arts on those of Persia. They present at the same time decisive evidence of one of the most congenial forms in which the Persian mind has preferred to express its artistic thought. What especially we discover at Susa is a form of Keramic painting, borrowed from that of Chaldæa, but surpassing it, an art which not only exhibits great technical skill but extraordinary ability in design. The procession of figures found there representing the Immortals, or royal guards, is hardly surpassed in the entire range of decorative art. The majesty of those forms, now brought after their sleep of ages in the mouldering earth to look again at the sun which their prototypes worshipped, prepares us to accept all that we read of the grandeur of Persia under Darius the Great. So late as the time of Shah Abbass, 1000 to 1630, pictorial plaques were made which rival the Keramic designs of Sufa, two thousand years earlier—an emphatic display of the persistence of a national instinct for a specific style of art expression. One of the most marked points in Keramic art was the invention of irridiscent glazes. This magnificent art was certainly discovered in Persia before the Mahommedan conquest. It became one of the most widely practiced arts of the Persians. Not only were vases thus made, but mural tiles for the decoration of mosques and shrines. There was a great variety of glazes, each irridescent like the elusive, mystic spark of the opal, or the shifting splendor of the dying dolphin, and yet each having a chromatic tone entirely its own. The secret of making this irridescent ware was lost in Persia about two centuries ago; but it is interesting to know that experiments for its revival are now being made in the United States, and have already given fair promise of success. The peculiar pendent decoration of vaults and niches, which has been carried to such an exquisite degree of elaboration in the Alhambra, is undoubtedly of ancient Persian origin, examples of it being still found in the ruins of Rhei. Another art which reached extraordinary excellence under the Sassanides, was the making of textile fabrics and embroideries of needlework. Printed calicoes have been manufactured there for ages. Block painting by hand was an original art in that country. The music of ancient Greece was borrowed from Persia. The spirit, the genius of Persian art yet pervades the intellectual atmosphere of the world. So long as her art influence is felt, she speaks to us a living language, and continues a civilizing power.

PROGRESSIVE REPOSE.

THE PHENOMENA OF SLEEPING AND WAKING.

Scientific investigators assert that in beginning to sleep the senses do not unitedly fall into a state of slumber, but drop off one after another. The sight ceases, in consequence of the protection of the eyelids, to receive impressions first, while all the other senses preserve their sensibility entire. The sense of taste is the next which looses its susceptibility to impression, and then the sense of smelling. The hearing is next in order, and last of all comes the sense of touch. Furthermore, the senses are thought to sleep with different degrees of profoundness. The sense of touch sleeps the most lightly and is the most easily awakened; the next easiest is the hearing; the next is the sight, and the taste and smelling awake last. Another remarkable circumstance deserves notice; certain muscles and parts of the body begin to sleep before others. Sleep commences at the extremities, beginning with the feet and legs and creeping toward the centre of nervous action. The necessity for keeping the feet warm and perfectly still as a preliminary of sleep is well known. From these explanations it will not appear surprising that, with one or more of the senses, and perhaps also one or more parts of the body, imperfectly asleep, there should be at the same time an imperfect kind of mental action, which produces the phenomena of dreaming.

ENTERPRISING WOMAN.—Mrs. Schliemann says she proposes to continue the excavations at Sissurlik, and that they will be carried out in conformity with Dr. Schliemann's plans under the direction of Dr. Dorlfield.

THE ABBOTT MEMORIAL.—A granite monument for Emma Abbott is being constructed at Quincy. It is to cost $85,000, and will be placed over the remains of the singer and her husband in the family lot at Gloucester.

THE DEADLY CIGARETTE.—If any one were discovered putting arsenic and phosporous in the cigars which men use, how soon a law would be found or made to fit his case. But when the same poisons are employed in preparing cigarette wrappers, with fatal results to two boys, there is no mention made of legal proceedings contemplated or begun. Anti-cigarette legislation is practically a failure, but there is no good reason why a law against poisoning tobacco should not be made a success.

MRS. LYNN LINTON WAILS.—There is no question that there is less modesty among women than there used to be. Modesty, indeed, is at a discount all through. From the callous *aplomb* of the platform orator to the suggestive undress of the fashionable woman we look in vain for that personal reserve which has hitherto been supposed to form part of the inventory of feminine graces. The modern studies, too, of women help in the destruction of that older reserve. Medical schools and the "life schools" in art may be of absorbing interest to the student, and of future emolument to the professor; but they kill something in the girl which is more valuable to the race than that such and such a Mary or Emma should understand all about diseases and their remedies, or how to draw the nude human figure with more or less accuracy.—*London Graphic.*

FOOD AND DIGESTION.

OPERATION OF FOODS AND MEDICINES UPON THE HUMAN GASTRIC JUICE.

An interesting paper on the above subject was published in a recent issue of the *Zeitschrift fur Klinische Medizine*, of which the subjoined is an abstract: The author, in making a series of experiments upon the influence of various articles of diet and medicine upon the gastric juice, first ascertained the ordinary amount of acid present in the stomach of the person experimented upon, and the time of its disappearance after Ewald's test meal, consisting of a roll weighing about an ounce and a quarter and ten ounces of water, and used the results as a standard for comparison. When certain quantities of alcohol were added in the shape of 50 per cent. cognac or Munich beer, the conclusion arrived at was that small quantities of alcohol, about 20 per cent., have a slight power of raising the HCl secreted, but in larger doses, 30 per cent. or over, they hinder the secretion and peptonization. Besides, the experiments show that, when regularly used, the stomach, after a time, fails to respond to its usual stimulus, the food; the required amount of stimulus becomes greater, the use of alcohol more frequent, the glandular function of the stomach becomes more and more affected, and the way is opened to the whole train of dyspeptic symptoms, ending at last in atrophy. Concerning the influence of coffee in infusion he can give no information, because the color of the beverage interferes with the reaction of color tests. He substituted, therefore, caffeine, which he administered in the form of powders along with rad. althæa. The result is that in doses of 20 cg., and still more in larger quantities, it has the property of lessening the total acidity at the height of indigestion; it also lessens the secretions of HCl, and delays peptonization. Since that amount of caffeine exists in the quantity of coffee taken usually by men, and more especially by women, we may assume that it has a similar action upon them. Nicotine was next experimented with, a certain quantity—one mg.—being introduced by the sound after a test meal. Only three patients were tested, and of these, in two cases, there was a very slight rise in the acidity; in the third, a slight rise also at first, but after several days' use a material lessening of the secretion and delay in peptonization. The experiments are admitted to be too few to draw safe conclusions from. Turning to the action of bitters on the secretion, Dr. Wolff refers to the experiments of Tschelzoff on animals, and Jaworski on men, which show that these drugs lessen the secretions of acid to such a degree that Jaworski attributes the commonly supposed beneficial employment of them in dyspepsia to their influence in lessening the acidity where hypersecretion exists. Wolff tested first the action of nitrate of strychnia in doses of 0.5–1.5 cg. The effect was found to be that where the acidity was below the normal, strychnia considerably raised it, but where HCl was habitually absent, the drug failed to call it forth. Infusion of cundurango seemed to have no (or very little) influence on the acidity, but a slight increase of the secretion of pepsin may be produced. Reichmann's experiments, a review of which was published in the *Chronicle*, gave nearly the same result. Bitter infusions poured into the fasting stomach produced less secretion than plain water, but when administered along with food the bitter quickly disappears, and the secretion is afterwards considerably increased; where, however, alkaline or neutral juice is ordinarily present, bitters are unable to provoke the secretion of HCl. Three persons were experimented on with 15 to 20 c. cm. of ox gall, administered along with a test meal. It was found that the acidity was thereby lessened, but there was no considerable diminution of the HCl or hindrance to peptonization. Administering 5 g. of common salt with the test meal of patients either with lessened or increased secretion of HCl invariably lessens the amount of HCl present, in cases of hyperacidity to one-half, with a corresponding improvement in the symptoms. The beneficial action of such waters as Wiesbaden and Kissingen must, therefore, be chiefly attributed to the lessening of the secretion of HCl, but their influence on absorption and the motor function of the stomach may be beneficial, and that on metabolism generally must not be neglected. The author cites, before making experiments of his own on the action of Carlsbad salts, the results of the latest experiments of Jaworski, that "small quantities of Carlsbad water or salt stimulate the secretion of acid and the digestive activity, but when used in large quantity they stop the secretion and digestive power for several hours; that under this medication from day to day the activity of secretion and digestion constantly diminish, and at last the sensibility of the stomach to irritants is lessened to such an extent that no kind of food suffices to produce acid, and frequently not even pepsin secretion." Ewald found, however, that in ten persons subjected to a course of thermal water, and tested at frequent intervals during the time, half had slightly lessened acidity, the other half increased, and the lessening occurred in those who before the treatment had a high acidity. Jaworski has also found borax to act primarily as an irritant in small doses, but in large doses it causes a lessening or total drying up of the secretion. Wolff, on the ground of the experience obtained of the action of common salt, Carlsbad salt, and borax, has administered a powder of the following composition in cases of hyperacidity, with or without hypersecretion, with great success: Sulphate of soda, 30 g.; sulphate of potass, 5 g.; chloride of soda, 30 g.; carbonate of soda, 25 g.; sodæ bibor, 10 g.; half a teaspoonful three times a day, in half a glass of lukewarm water, fasting, and two hours before dinner and supper. In a typical case of hypersecretion the quantity of fluid in the fasting stomach was reduced, by four weeks' treatment, from 50 c. cm. to a few cubic centimeters, and the acidity, at the height of digestion, by one-third. Referring to the influence of acids on the secretion, Wolff found that when hydrochloric acid was administered to three patients in whom it was habitually absent, for periods of eight days, there was not in a single case any distinct action on the HCl secretion. A distinction ought to be made, perhaps, according to the results of Jaworski's experiments, between ordinary acids and carbonic acid, since the latter exercises a purely mechanical influence, and in some raises the acidity considerably, and increases the peptic power of the gastric juice.

UNSELFISHNESS.

THE SPLENDID NOBILITY OF SELF-FORGETFULNESS.

The wonderful life and work of Dorothy Dix afford a striking illustration of the lofty heights to which a soul may rise who sinks self. Miss Dix at an early age began teaching the street arabs and those who were too poor to pay for schooling. Later her attention was called to the frightful condition of the insane in Massachusetts where she lived at that time. A maniac was kept by whoever would bid the lowest. No ferocious wild beast received such terrible treatment as did the poor human being who had lost his mind; starved, penned in filth and often half frozen, the insane presented a sight too pitiful for words. Miss Dix personally investigated the matter; she asked no aid; from her own limited purse she paid all expenses. When an overwhelming array of facts had been collected, she appealed to the legislature where she met with fierce opposition; conservative thought, and a blunted public conscience and rascality assailed her. She faltered not until victory crowned her work, and the insane of this Commonwealth were better provided for than ever before. Then began her pilgrimage. She visited State by State; she revolutionized the treatment of the insane in America. But this was not enough; the most pitiable class in other lands were to be looked after. Accordingly she visited the various European nations even to the heart of Turkey. Everywhere victory crowned her efforts. When the War of the Rebellion broke out she immediately entered the hospitals and served as nurse during the long, weary struggle. After peace once more brooded over the Republic, she set about her old work of bettering the condition of the insane. Such was her glorious life. She shrank from fame and abhorred ostentation. She only asked to be allowed to work silently for those who most needed aid. Her life was as beautiful in reality as any angel vision that ever floated through artist's brain. Another well-known life which exemplified unselfishness in a marked degree was Wendell Phillips, the idolized son of the cultured and elect of Boston, the popular child of Beacon Hill, when he stood with the strongest probability of having given to him the highest honor he could ask from his State, if he was true to conservative and popular thought; while on the other side loomed up before him, duty in sombre garb and sackcloth, offering him no chaplet save the supreme gift of the ages so little valued to-day—consciousness of doing right. When he was forced to decide between the right with ignominy, scorn, and social ostracism ready to be heaped upon him; or the glory of his day for stifling conscience and obeying the dictates of fashionionable and conservative thought; when joy, ease, and the sunshine of popularity beckoned him from duty's dictates, he chose what he felt to be right, though he knew in so doing he closed against himself the bright vista down which he had so often and so fondly dreamed he would some day walk. This is an illustration of unselfishness worthy our emulation. Another noteworthy example of unselfishness was seen in the action of Dr. Guyon. A terrible plague was raging in Marseilles—it seemed that the entire population would be cut off. The physicians of the city were unable to stay the curse, not knowing the nature of the disease. The dissection of a corpse seemed to be the only means of giving the necessary knowledge, but the contagious nature of the disease and its fatality made it sure death to any one who undertook it. A counsel of physicians had for some time deliberated; finally Dr. Guyon, one of the most celebrated doctors of the city, and a man in the very prime of life, arose, saying: "So be it; I devote my life to the safety of my country." He dissected a corpse, and critically examined all conditions of the organism that would throw light on the nature of the malady. He then wrote out a careful, detailed description of the result of his investigations, placing the paper on which it was written in a vase of vinegar to prevent communicating the contagion to those who might read it, after which he retired to his apartments, where he died in twelve hours. One other example representing this spirit, though in a different way, was seen in the brave action of Grace Bussell. The steamer Georgette was stranded off Perth; a boat laden with women and children left the wreck, but was swamped by the surf. Clinging to the little bark, these victims of the ocean's caprice shriked wildly for aid, only to be mocked by the loud mocking of the billows. Suddenly over the hill-top and down the precipitous coast a young woman, mounted on a coal-black charger, came dashing along at break-neck speed. Arriving at the brink of the sea she paused a moment, then dashed forward into the water; her steed tried to turn, but she urged him on till the boat was reached. In this manner she made several trips, and succeeded in landing all who were alive. Then, almost fainting from fatigue and drenching wet, but thinking not of herself, she galloped home to send relief to the poor creatures she had rescued. We have taken these five illustrations from the innumerable instances of this kind that illuminate the history of every age, because they serve as examples of different phases of this lofty virtue, and because many people thoughtlessly regard its cultivation of little moment, when in truth it is one of the foundation stones on which true character rests. It is

a lesson in the higher education that is difficult to learn, but rich in its fruition—something that yields a harvest of happiness to others, and a hundred-fold to the one that acquires it. Not in the empty honor of funeral pageant, not in the brilliant eulogium of gifted orators, not in the splendor of costly sepulchres, do the true and the noble perpetuate their names and their callings on earth, but in the sweet fragrance that follows their unselfish lives, by the beauty that lingers in their deeds long after their spirits have been promoted.—*B. O. Flower in Spectator.*

LUNG GYMNASTICS.

HOW TO RELIEVE AN OVERWORKED BRAIN.

A Swiss doctor says that many persons who extend their mental work well into the night, who during the evening follow attentively the programme of a theatre or concert, or who engage evenings in the proceedings of societies or clubs, are awaked in the morning or in the night with headache. He is particular to say that he does not refer to that headache which our Teutonic brethren designate *Katzenjammer*, that follows certain convivial indulgences. This headache affects many persons who are quite well otherwise, and it is due in part to the previous excessive work of the brain, whereby an abnormal flow of blood to that organ is caused; in part to other causes, for example, too great heat of rooms, contamination of the air with carbolic acid, exhalations from human bodies, and tobacco smoke. For a long while the doctor was himself a sufferer from headache of this kind, but of late years has wholly protected himself from it by simple means. When he is obliged to continue his brain work into the evening, or to be out late nights in rooms not well ventilated, instead of going directly to bed he takes a brisk walk for half an hour or an hour. While taking this tramp he stops now and then and practices lung gymnastics by breathing in and out deeply a few times. When he then goes to bed he sleeps soundly. Notwithstanding the shortening of the hours of sleep, he awakes with no trace of headache. There exists a clear and well-known physiological reason why this treatment should be effective.

DOMESTIC DIETETICS.

SPECIALLY PREPARED, FROM PRACTICAL TESTS, FOR THE LADY READERS OF THE "AMERICAN ANALYST."

SEASONABLE FOOD.

June.

MEAT.—Beef, lamb, mutton, ham, kidneys, liver, sausage, veal.

GAME AND POULTRY.—Pigeon, chicken, duck.

FISH.—Anchovy, bass, bluefish, blackfish, cod, eels, clams, flounder, haddock, halibut, herring, lobsters, mackerel, mussels, perch, porgie, prawn, salmon, shad, turtle, trout, sturgeon, whiting, weak-fish.

VEGETABLES.— Beans, cucumbers, carrots, cauliflower, lettuce, onions, parsley, parsnips, potatoes, shallots, spinach, turnips, radish, rhubarb.

FRUITS.— Cherries, strawberries., bananas, pineapples.

PRACTICAL RECIPES.

TURNIP SOUP.—Cut a piece of the scrag of mutton, about two pounds, into small pieces, and put them to cook into five quarts of cold water; when it begins to boil skim well and set it where it will stew gently for three hours or until the meat falls to pieces; then strain through a colander and let it get cold. Skim off the fat and add light turnips peeled and cut into thick slices and half a cup of rice. Cook gently until the turnips are soft, then season.

BOILED TONGUE AND TOMATOES.—Select a fresh tongue; wash, trim and scrape it, and cook it for three-quarters of an hour in cold water; put it in a pot, cover with hot water and cook until it is tender, then take it out of the water, peel off the skin, lay it on a hot platter and pour over it some tomatoes prepared as follows: Peel some tomatoes and slice them thin and put with them some fine dry crumbs—enough to thicken them when done; put them in a kettle, and cook gently, stirring frequently; add to them half a small onion and five or six cloves, and when done take out the onion and cloves and add a large spoonful of butter, pepper and salt. Have this ready when the tongue is done; pour it around the tongue on the platter and serve very hot.

BROILED TOMATOES.—Select fine firm tomatoes and cut them in thick slices. Put them between the wires of a toaster and cook for a moment first on one side, then on the other; pour over them some melted butter in which there is pepper and salt and a very little onion juice, and serve very hot.

BAKED CHICKEN WITH TARTARE SAUCE.—Take a chicken and split it down the back; wipe it carefully with a damp cloth, spread it all over with butter, dredge with salt and pepper and bake until very tender, then serve with tartare sauce.

TARTARE SAUCE.—Mix together the yolk of a hard boiled egg, the yolk of an uncooked egg, a teaspoonful of mustard, a teaspoonful of sugar, a teaspoonful of salt and a quarter of a teaspoonful of pepper. Now add a little at a time, stirring carefully, half a small bottle or half a teacup of olive oil. This should make a stiff mixture. Add vinegar to taste, probably about three tablespoonfuls of it. Then grate in a little onion —very little—and add a tablespoonful each of chopped capers and pickles. Cayenne pepper may be added. Without the capers and pickles this is mayonnaise.

BATH BUNS.—Take some regular bread dough that has been raised till light, about four pounds, and spread it on a board and add to it the following ingredients after they have been mixed together. The yolk of four eggs, six ounces of butter, eight ounces of lump sugar broken into small pieces but not crushed, the candied peel of a lemon chopped fine and a little lemon juice. Mix these ingredients thoroughly into the dough and then divide the dough into pieces the size of a biscuit and lay them in well-greased tins; set to rise till they are very light, then wash over with egg, put some powdered sugar on top of each and bake.

GINGER CAKE.—One and a-half pounds flour, one-half pound brown sugar, one-half pound butter, one pint molasses, three large tablespoonfuls of ginger, one tablespoonful of sweet lard, cinnamon, mace and grated lemon rind. Roll out very thin.

PINEAPPLE SHERBET.—Cut up a ripe pineapple into small bits, sprinkle it with sugar and set away for several hours, then pour off the juice and squeeze out all that remains in the fruit. To one pint of juice add one pint of water, the juice of a large fresh lemon, and enough sugar to make it very sweet before freezing. Freeze, and when it is nearly done add to each quart the white of an egg beaten up very stiff and sweetened with powdered sugar. Mix thoroughly into the ice and freeze until stiff.

LITTLE CAKES.—One and one-quarter pounds of flour, one pound of powdered sugar, one pound of butter, eight eggs. Beat the sugar and butter to a light cream, adding in the eggs gradually while doing so. Work in the flour; spread the mixture in two very shallow buttered tins and bake in a moderate oven. When cold cover with peach or other jam, put two together and ice, and while wet sprinkle thickly with ground sweet almonds and cut into little squares or diamonds.

AIR.

HOW ITS MOTION IS IMPARTED AND CONTROLLED.

The air is in constant motion, and every current of air, from the lightest zephyr to the blast of the hurricane, is called wind. The force which sets and maintains it in motion is the warmth from the sun's rays. These pass through the air without appreciably warming it, but impinging upon the surface of earth and ocean they are absorbed; and the heat being again radiated, warms the atmospheric strata nearest the surface. But the ratio in which the different regions of the earth are warmed varies considerably. Around the the equatorial belt the sun's rays fall vertically, or nearly so, and the heat is absorbed in a narrow area, but in higher latitudes the slanting rays diffuse an equal amount of warmth over a wider area. The zone of the greatest heat has its centre north of the equator, owing to the fact that there is more dry land in the Northern Hemisphere, and that solid bodies absorb and radiate more heat than water. Over this warm region, which by no means covers the whole tropic zone, the heated air at the surface, becoming lighter by expansion, ascends through the cooler strata above it. It could not, however, continue to rise unless it were replaced, and this occasions the inrush from north and south of cooler air, which in its turn gets warmed and ascends. The ascent of the upward currents is arrested as they reach a rarer atmosphere, and being debarred from falling back by the presence of ascending currents from below, they take a horizontal course towards the poles. A vertical ascending current of air is not regarded as a wind, because there is no horizontal motion attending it, and the zone of ascending columns is consequently dreaded by the sailors as the region of calms. Occasionally the calm is interrupted by thunder-storms, due to the watery vapor which the ascending currents carry up with them. This, by its condensation in the upper atmosphere, forms clouds from which thunder-storms break out, liberating the heat, which gives a new impulse to the ascending currents. The warm, moist air rising from the region of calms, and taking its course towards the poles, does not remain in the upper air. Even before it leaves the tropic regions it divides, giving off a vertical descending current, which, reaching the lower cool currents, is borne back to the torrid zone again. The regions through which it passes are again characterized by calms and storms. The main current, after having given off this descending current, continues its course towards the pole, approaching the surface of the earth nearer and nearer, until it reaches it in the temperate zone. Thus arises a double circulation, the lesser caused by that portion of the ascending current which descends near the edge of the tropics and flows back to the equator; the greater caused by the main volume, which, descending gradually in higher regions, and becoming cooled, flows back over the surface towards the equator, and is known, within the tropics, as trade winds. This double circulation would occur uniformly in all meridians if the earth stood still, but as a consequence of the earth's motion every current of air on the surface is appreciably deflected from its original course. As the earth revolves on its axis, from west to east, in twenty-four hours every part of its surface, with its atmosphere, describes a circle greatest at the equator and lessening towards the poles. While a point on the equator is travelling 463 miles from west to east, a point under 45 deg. lat. traverses only 326 miles, and under 60 deg. lat. only 231 miles. Every place takes its own atmosphere along with it. If, then, a volume of equatorial air travelling at a speed of 463 miles an hour were suddenly transferred to the latitude of 45 deg. where the air has a speed of only 326 miles, it would generate a gale rushing from west to east at a speed equal to the difference, *i. e.*, 137 miles an hour; while a volume of air transplanted from 45 deg. lat. to the equator would create a terrific hurricane from the east. Happily such sudden transfers, with their violent consequences, do

not actually occur. Nevertheless the aerial currents, on their way from the equator to the poles and back again, are subject to the influence of the earth's revolution, only gradually, and for that reason with less violent results. The equatorial current, apart from its drift from south to north, is also subject to the motion from west to east, imparted to it by the speed of the earth's revolution at its birthplace on the equator; and traversing regions in which the speed from west to east is steadily diminishing, it is deflected from its course of south to north, in an easterly direction, until the original south wind becomes a sou'wester. On the same principle the Polar or return current, on its way to the tropics, entering regions in which the rate of revolution is increasingly higher, gets left behind at every stage, until the original north wind becomes a nor'easter in the tropics. The trade wind in the Northern Hemisphere has consequently one invariable direction, entering the tropics as a nor'easter. No wonder, then, that Columbus's sailors, who knew nothing of the trade winds, argued, from the prevalence of the nor'easter on their outward course, that they would never be able to return to Spain. The upper or counter trade winds, subject to the same law, pursue an opposite course, at a height far above that of the highest mountains; the dust from volcanoes is, nevertheless, sometimes projected into and borne along by them.

MASCOTS AND TALISMEN.

LUCKY OBJECTS WHICH PEOPLE CARRY TO INSURE GOOD FORTUNE.

Almost every one has a belief in luck. Some call it fortune. Some go so far as to describe it as providence. A lucky hit, a fortunate chance, a Providential escape—these are every day phrases by all sorts and conditions of men. There is a story told of a clergyman of the Church of England, who, when he was going to preach, always conveyed a little old-fashioned bookmarker to the pulpit and laid it upon the desk. It had been made by his grandmother years before, and had the words "turn over" worked in green (now faded) silk upon it. The clergyman had possessed it from boyhood, and it represented to him a command to proceed, to strive, to succeed. It was his mascot, his luck. Numbers of people keep in their pocketbooks a little piece of dried-up stuff wrapped in a piece of tissue paper. Ask what it is, you will be told it is the tip of a beef tongue. It is carried for luck. In the records of the lost property offices that tongue tip is often mentioned. It has frequently served as a means of identification, for the superstition is that the purse which contains the "tip of a tongue that never told a lie," can never be lost. And talking of purses suggests the ancient custom of handsel. To make any one a present of a pocketbook without having first placed in it a coin of some value is to give poverty instead of wealth, and the fortune, or luck, will be in proportion to the value of the handsel. In England and Scotland no beggar will start upon his tramping excursion in the spring without half a horseshoe concealed somewhere about his person. This is known throughout the canting fraternity as "beggar's luck." The once famous King of the Beggars, Bamfylde More Carew, was never without this bit of old iron, as is told by himself in his autobiography. The old iron theory of luck is mainly practised by people whose business or inclination leads them to wander. There is a French actress now traveling in this country who is never without an old nail in her pocket. Among French and Russian actresses especially the "clou" is indispensable to good fortune. Soldiers' luck is generally dependent upon the possession of an old button cut from the coat of a dead soldier, and if it be from an enemy so much the luckier. This fancy exists in all European armies, and it is quite possible that among the soldiers of our own small army some similar superstition exists. A decidedly quaint superstition in this city is cooks' luck. It is a portion of a bowl of an old silver spoon. It had been worn so thin with age that the handle had first been broken off and then the bowl had split in two. A certain chef in New York carries the remaining half of the bowl "for luck." And he would not part with it for anything. That a tailor should be a trifle superstitious is not very surprising, perhaps, but the object of their fetish worship is peculiar. A piece of white clarified beeswax is the favorite. Possibly it is supposed to represent the toughness of the thread used, but at any rate in many a snip's pocket will be found the bit of wax carefully preserved, never used except to touch with the tips of the fingers before beginning any fresh work in order to insure a lucky conclusion. Shepherds' luck" consists of the thyroid bone of a lamb. The tiny, partially ossified cartilage is carefully abstracted from the first born of a flock when it is killed. It must be the first born or it is of no use. Every lamb born thereafter is rubbed gently with this to keep witches away, and if a sheep or lamb falls sick the touch of this talisman is of more value than any medicine.

MENTAL EFFORT.

UTILIZING ELECTRICITY AS A MEASURE OF THOUGHT.

Mr. J. L. Balbi says: It is well known to the medical profession that every mental effort causes a rush of blood to the brain, and that the amount of blood depends on the "intensity of the thought; but rush of blood means a rise in temperature, and if we could measure this we would be able to determine in a rough way, the "power necessary for the generation of any thought or mental effort. I accomplish this object in the following manner: I have a head gear of some light, high-conducting (heat) substance. In its middle or any other convenient position I fix a thermo-electric pile, and connect this, by means of flexible wires or otherwise, to a sensitive galvanometer. The extreme sensibility of the thermo-electric pile is well known, and therefore whatever rise in temperature takes place, consequent to the rush of blood, would be instantaneously indicated by the galvanometer. The utility of such an apparatus may not appear at first sight of great importance, but if we consider for an instant the facility or difficulty with which children at school learn their lessons, any doubts we may have entertained as to its practicability will be immediately dispelled. By such a contrivance would we ascertain the "brain power" of boys and girls, nay, even men, and thus be in a position to indicate in what direction their mental efforts ought to tend.

FASHIONABLE JEWELS.

SNAKES, REPTILES, AND JOAN OF ARC'S SWORD.

A new fad in jewelry has seized the ladies of Paris. The real Parisienne must have a jeweled fad. And one of the peculiarities of this tendency is that it invariably runs to animals, insects, living creatures of the lower orders, venomous, repulsive or suggestive. It was not long ago when the haute monde dangled gold and silver elephants from their bracelets or rings. Then they evoluted and adopted the "American hog," and Chicago was properly represented on the fair neck, or wrist, or at the belt of every dashing wearer of Worth's or Felix's outfits. So now it is Cleopatra's asp. The deadly creature is made in diamonds and glitters instead of bites. Of course it was "la deesse Sarah," the reincarnation of the "Serpent of Old Nile," the—but why multiply expletives? You have her with you and can make them for yourselves. It was she who inspired the fashion, as she has inspired a score of others, and the beau monde rushes wildly in the wake. The idea of an asp has evolved other cognate reptiles, and so one is not surprised to see specimens of the natural order lacertilla, which the vulgar call lizards, glistening in all the colors of their varied hues. They are made of diamonds and sapphires, and to a sensitive soul loathsomely natural. But that matters not to the votaries of the fashion, who not long ago attached live beetles by little gold chains to their bodices, like the Mexicans, and let the little beasties crawl over their white necks, or imprisoned glow worms in the mazes of their tulle draperies. But there is another exceedingly popular bauble which deserves to be chronicled because it also owes its being to the adoration which is offered at the shrine of La Bernhardt, and to the exquisite purity and fervor which she seemed to breath forth in her performance of "La Pucelle," and proves that she can, by the imaginative power of her heart, at once sink to the depth of degradation, or rise to the height of exquisite purity. This piece of bijouterie is the Joan of Arc sword, as the jewelers call it. It is worn on all occasions, and even sparkles at the throat of the fair owner when she wears a high bodice. The rule that obtains now in the wearing of jewels is, that the largest of the lot shall be used as a buckle at the waist, while the earrings are small and usually consist of a single stone, an emerald, a turquoise or a sapphire, which may, however, be surrounded by diamonds. There is now a definite rule, too, with regard to the wearing of bracelets. Hitherto, a lady might go to breakfast in a wrapper with a score of jingling metal circlets adorning her more or less white and fragile wrist, but now all this is changed. No one who is any one is ever seen in daylight with a bracelet, even in the afternoon. Madame or mademoiselle, when she takes her walk abroad, must have her wrist covered only with her gloves. But at night the jewels get their innings. Then every one may be taken from the jewel case and put on so that miladi may resemble that heroine of the nursery rhyme, who wore rings on her fingers and bells on her toes, as far as the jingling she makes with her bangles goes.—*Western Jeweler.*

LIQUID FUEL.

PETROLEUM SUPERIOR TO COAL FOR VESSELS OF WAR.

At a recent meeting of the Shipmasters' Society, London, a paper was read on "Liquid Fuel in Ocean Steamers." Premising that the question of liquid fuel in steamers was not a new one, the lecturer stated that, partly owing to the cheapness of coal, and partly to the timidity of owners to adopt it, the use of oil fuel had not been much taken up by steamship owners. Now, however, the aspect of affairs was changing. By the use of petroleum, he stated, that the fires were completely under the control of the engineer on watch, who would regulate them so as to have any pressure of steam he required, without being dependent on his firemen. The great advantage of oil fuel to the shipowner was that he could carry his fuel in a space that was now wasted, namely, a cellular bottom of the ship, or in his ballast tanks. As the consumption of oil, compared with coal, was, weight for weight one-half—ten tons of coal, in other words, being only equal to five of oil—the storage of fuel could be made much more compact and easier of access; There was increased speed in the fuelling the ship; and port charges were avoided, as more fuel could be carried in proportion than formerly. Petroleum was known to exist in all parts of the habitable globe, and it was hardly probable that competition would not bring the fuel within easy reach of the commercial world. For many reasons oil fuel was of more value to torpedo boats and ships of war than it probably was to merchant steamers. As to the question of fueling our men-of-war at sea during a blockade, he thought that the large tank steamers of the present day could always fuel the fleet even in heavy weather. He maintained that the oil was perfectly safe while on board ship: that it could be stored on shore easily, and in the event of a fueling

Indigestion

Horsford's Acid Phosphate.

A preparation of phosphoric acid and the phosphates required for perfect digestion. It promotes digestion without injury, and thereby relieves those diseases arising from a disordered stomach.

Dr. E. J. WILLIAMSON, St. Louis, Mo., says: "Marked beneficial results in imperfect digestion."

Dr. W. W. SCOFIELD, Dalton, Mass., says: "It promotes digestion and overcomes acid stomach."

Dr. F. G. MCGAVOCK, McGavock, Ark., says: "It acts beneficially in obstinate indigestion."

PURE PEPSIN

In Powder and Scale.

MANUFACTURED BY

ARMOUR & COMPANY, Chicago.

Guaranteed free from adulteration or make-weights; of excellent physical properties and high digestive power.

Under similar conditions, **ARMOUR'S PEPSIN** will exhibit greater activity than any other pepsin now before the profession.

The Manufacturers will be pleased to supply members of the Medical Profession with samples of their Pepsin, and with full details regarding digestive strength, if desired.

port being bombarded, shells could not set fire to the tanks; and it could be handled without risk of fire or explosion from the shore to the ships, or *vice versa*. His object in reading the paper had been to allow the mercantile world in general, and the members of the Shipmasters' Society in particular, to know the progress oil fuel was making; the comfort it was to engineers and all concerned; its pecuniary advantages to the merchant who could avail himself of it; its peculiar adaptability to ships of war; and its special value to large, first-class passenger steamers, where cleanliness and the comfort of the passengers were desired. It could be adapted to any boiler, either afloat or ashore.

SUBTERRANEAN FIRES.

GRAPHIC DESCRIPTION OF A SANDWICH ISLAND VOLCANO.

Some idea of the terror of volcanoes may be gathered from an account of an eruption in one of the Hawaiian Islands, as graphically described in the *London Budget*, when the crater was filled from five hundred to six hundred feet deep with molten lava, the immense weight of which broke through a subterranean passage of twenty-seven miles and reached the sea, forty miles distant, in two days, flowing for three weeks and heating the water twenty miles distant. Rocks melted like wax in its path; forests crackled and blazed before its fervent heat; the works of man were to it but as a scroll in the flames. Imagine Niagara's stream above the brink of the falls, with its dashing, whirling, madly raging waters, hurrying on their plunge, instantaneously converted into fire—a gory-hued river of fused minerals; volumes of hissing steam arising; smoke curling upward from ten thousand vents, which give utterance to many deep-toned mutterings and sullen, confined clamorings; gases detonating and shrieking as they burst from their hot prison house; the heavens lurid with flames; the atmosphere dark and oppressive; the horizon murky with vapors and gleaming with the reflected contest. Such was the scene as the fiery cataract, leaping a precipice of fifty feet, poured its flood upon the ocean. The old line of coast, a mass of compact, indurated lava, whitened, cracked and fell. The waters recoiled and sent forth a tempest of spray; they foamed and lashed around and over the melted rock, they boiled with white heat, and the roar of the conflicting agencies grew fiercer and louder. The reports of the exploding gases were distinctly heard twenty-five miles distant, and were likened to a whole broadside of heavy artillery. Streaks of the intensest light glanced like lightning in all directions; the outskirts of the buring lava as it fell, cooled by the shock, were shivered into millions of fragments and scattered by the strong wind in sparkling showers far into the country. Six weeks later at the base of the hills the water continued scalding hot and sent forth clouds of steam at every wash of the waves.

FISH EXHIBIT.—The Fish Commission's exhibits of aquaria at the Chicago Fair is to be immensely attractive. As thus far conceived, though details have not been perfected, the annex for the purpose will be 150 feet square and entirely of glass. There will be 1,000 feet in length of glass tanks filled with all sorts of water creatures, one-half being devoted to marine life and the other half to the display of fresh-water specimens. The visitor will walk between two lines of aquaria the entire circuit of the building. In the middle of the latter will be a great tank full of salt water brought all the way from the Atlantic.

BOILER SCALE EXPENSIVE.—Experiments made 20 years ago on the non-conducting properties of boiler scale gave astonishing results. The effect of the scale accumulation is given as follows: $\frac{1}{16}$ inch thick requires 15 per cent. more fuel; $\frac{1}{4}$ inch 60 per cent. more fuel, and $\frac{1}{2}$ inch thick 150 per cent. more. To produce steam at 90 pounds pressure, in a clean boiler, only 355 degrees of heat are required, but with heavy scale this temperature must be increased 200 to 300 degrees. For $\frac{1}{2}$ inch of scale the heat must be 700 degrees, or almost a low red heat for the iron.

ARMOUR & CO., Chicago.

"ONE BILLION."—When one speaks of a billion in in England or Germany, a million million (1,000,000,000,000) is understood, but in the United States, as in France, Spain and elsewhere, the term is used to signify a thousand million only (1,000,000,000). It would therefore be well for the German-American press to to employ the term in this sense, precisely as we employ the word mile to signify an English mile and not a German or any other mile.— *Deutsche Allgemeine Zeitung* (*Chicago*).

HIGH, BUT CHEAP.—Chicago will soon have the largest ten-cent lodging house in the world. The building will be seven stories high, will cost eighty-five thousand dollars, and will be heated by steam and lighted by electricity. Each of the three hundred and sixty rooms will be seven by six feet, provided with iron bedsteads and hot and cold water. The floors will be of tile and the wainscoting of marble.

IMITATION GROUND GLASS.—Put a piece of putty in muslin, twist the fabric tight and put it into the shape of a pad; well clean the glass first, and then treat it with putty all over. The putty will exude sufficiently through the muslin to render the stain opaque. Let it dry hard and varnish. If a pattern is required, cut it out in paper as a stencil, place it so at not to slip, and proceed as above, removing the stencil when finished. If there should be any objection to the existence of the clear spaces, over it with lightly opaque varnish. In this way very neat and cheap designs may be painted on glass doors.

THE FAMILY CYCLOPÆDIA OF USEFUL KNOWLEDGE.

This is unquestionably one of the most interesting, entertaining and instructive books ever published. It is a universal educator for every member of the family circle, filled with useful information from beginning to end, and this information is given in such an attractive and pleasing way that the book is quite as entertaining as it is instructive. It treats of hundreds of subjects of which no man, woman or child who seeks to be well informed can afford to be ignorant, yet of which the masses of people are entirely unlearned. It contains the cream or substance of a dozen ordinary volumes, and is one of the most valuable and useful books a family can have in the house. No living man is so well informed that he may not learn from it. It is a book for the masses, for old and young, rich and poor, and will be read with pleasure and profit by all. It will likewise be found of great value as a work of reference. The book is profusely and elegantly illustrated, and is conveniently divided into departments, as follows: ***Biography, History, Natural History, Travels, Manners and Customs, etc.; The World Illustrated, Useful Arts and Manufactures, Trees, Plants, Fruits, etc.; Great Inventions, Mining, Wonders of the Sea, Familiar Science, Law for the Masses, Statistical and Miscellaneous.*** All the above subjects are fully and ably treated in this valuable book. It is a vast storehouse of useful and entertaining knowledge—unquestionably one of the best and most valuable books ever published in any land or language. No cyclopædia ever heretofore published at twice the cost is to be compared with this book in point of artistic make-up, beauty, and excellence of illustration, and quality of contents. As a holiday or birthday present for any one, nothing more appropriate or acceptable could possibly be selected. THE FAMILY CYCLOPÆDIA OF USEFUL KNOWLEDGE is a large and handsome book of 544 pages, 12mo, printed upon fine paper and elegantly bound in cloth, embellished with artistic designs in black and gold. It contains ***Two Hundred and Seventy-three Beautiful Illustrations,*** the original cost of which was over $5,000. The book will be sent by mail, post-paid, to any person sending a ***New Subscription with One Dollar.*** It is as large and handsomely gotten up as books usually sold at $1.50 and $2.00, and in the quality of its contents is worth a dozen ordinary volumes

GRAND PREMIUM OFFER!

A SET OF THE

WORKS OF CHARLES DICKENS,

In Twelve Large Volumes,

Which we Offer with a Year's Subscription to this Paper for a Trifle More than Our Regular Subscription Price.

CHARLES DICKENS.

Wishing to largely increase the circulation of this paper during the next six months, we have made arrangements with a New York publishing house whereby we are enabled to offer as a premium to our subscribers a **Set of the Works of Charles Dickens,** in **Twelve Large and Handsome Volumes,** with a year's subscription to this paper, for a trifle more than our regular subscription price. Our great offer to subscribers eclipses any ever heretofore made. Charles Dickens was the greatest novelist who ever lived. No author before or since his time has won the fame that he achieved, and his works are even more popular to-day than during his lifetime. They abound in wit, humor, pathos, masterly delineation of character, vivid descriptions of places and incidents, thrilling and skillfully wrought plots. Each book is intensely interesting. No home should be without a set of these great and remarkable works. Not to have read them is to be far behind the age in which we live. The set of Dickens' works which we offer as a premium to our subscribers is handsomely printed from entirely new plates, with new type. The twelve volumes contain the following world-famous works, each one of which is published *complete, unchanged, and absolutely unabridged:*

DAVID COPPERFIELD,
MARTIN CHUZZLEWIT,
NICHOLAS NICKELBY,
DOMBEY AND SON,
BLEAK HOUSE,
LITTLE DORRIT,
OUR MUTUAL FRIEND,
PICKWICK PAPERS,
BARNABY RUDGE AND CHRISTMAS STORIES,
OLIVER TWIST AND GREAT EXPECTATIONS,
THE OLD CURIOSITY SHOP AND THE UNCOMMERCIAL TRAVELER,
A TALE OF TWO CITIES, HARD TIMES AND THE MYSTERY OF EDWIN DROOD.

The above are without question the most famous novels that were ever written. For a quarter of a century they have been celebrated in every nook and corner of the civilized world. Yet there are thousands of homes in America not yet supplied with a set of Dickens, the usual high cost of the books preventing people in moderate circumstances from enjoying this luxury. But now, owing to the use of modern improved printing, folding and stitching machinery, the extremely low price of white paper, and the great competition in the book trade, we are enabled to offer to our subscribers and readers a set of Dickens' works at a price which all can afford to pay. Every home in the land may now be supplied with a set of the great author's works.

OUR GREAT OFFER

TO SUBSCRIBERS

TO THE

AMERICAN ANALYST.

We will send the **ENTIRE SET OF DICKENS' WORKS,** *in* **TWELVE VOLUMES,** *as here described, all postage prepaid by ourselves, also* **THE AMERICAN ANALYST** *for* **ONE YEAR,** *upon receipt of* **$1.50,** *which is only* **50** *cents more than the regular subscription price of this paper.* Our readers, therefore, practically get a set of Dickens' works in twelve volumes for only 50 cents. This is the grandest premium ever offered. Up to this time a set of Dickens' works has usually been $10.00 or more. Tell all your friends that they can get a set of Dickens' works in twelve volumes, with a year's subscription to **THE AMERICAN ANALYST** for only **$1.50.** Subscribe now and get this great premium. If your subscription has not yet expired, it will make no difference, for it will be extended one year from date of expiration. We will also give a set of Dickens', as above, free and post-paid, to any one sending us a club of three yearly subscribers.

Tabasco Pepper Sauce

OR LIQUID PEPPER.

Is simply the Pulp of the Ripe Pepper Extracted by Pressure.

The seed of this Pepper was obtained from Central America, and by careful cultivation in Louisiana for many years has been so improved in strength, flavor and aroma, as to have become a new variety of Red Pepper, superior to all others. The pulp is so handled as to retain all the flavor, strength, aroma and color of the ripe fruit, and to keep unimpaired in any climate. It excites the appetite, promotes digestion, and is pronounced, by connoisseurs, to be the finest condiment in the world. For medicinal purposes it recommends itself by its purity, strength and diffusible form.

Manufactured by E. McILHENNY,

NEW IBERIA, LA.

For Sale by all Wholesale Grocers.

To Subscribers, Readers and Advertisers.

SUBSCRIBERS' attention is called to the great variety of interesting and instructive subjects treated in this number. We respectfully ask the co-operation of our subscribers in extending our Subscription list, which will enable us still further to increase the value of the AMERICAN ANALYST to them.

The CASUAL READER is specially requested to examine our liberal premium offer.

ADVERTISERS who do not know of this Journal already, are respectfully referred to article headed "A Business Benefit."

ALL are kindly requested to peruse this number thoroughly.

The AMERICAN ANALYST can be had at any news stand in the United States. Any newsdealer will take orders for it, the American News Company being our wholesale agents. All postmasters will receive subscriptions.

NATRONA BI-CARBONATE OF SODA.

(ABSOLUTELY PURE.)

The nature of the raw material from which NATRONA BI-CARBONATE OF SODA is made—viz., kryolith, a mineral containing *pure sodium*—insures a purity and uniformity of product which cannot be obtained from any other known material. In making BI-CARB. SODA from any other raw material, the use of sulphuric acid is a necessity, but none is used in any part of the process of making NATRONA BI-CARB.; hence its entire freedom from the slightest trace of arsenic, which is always present in ordinary soda. Its absolute purity and entire freedom from all traces of *sulphate of soda*, common salt and other impurities, render NATRONA BI-CARB. NEARLY TASTELESS, and being bolted through the finest bolting-cloth, insures the finest stage of division.

To these indisputable facts the attention of CONSUMERS of soda is specially called. They are IMPORTANT, and should influence both those who use and those who sell soda, to buy and sell NONE BUT THE BEST.

The NATRONA BI-CARB. Soda is kept in stock by almost every wholesale druggist and grocer throughout the United States, of whom it may be ordered.

Natrona Bi-Carb. Soda is unequaled by any other brand of English or American Manufacture.

INSTRUCTIONS TO SUBSCRIBERS.

The **Names of all Subscribers** are registered as soon as received, and paper is always promptly forwarded.

Postage.—The postage to all parts of the United States and Canada is paid by the publisher.

Remittances of small sums may be made with comparative safety in ordinary letters. Sums of one dollar or more must be sent by registered letter or P. O. money order, otherwise we cannot be responsible for same. Silver must not be sent in a letter.

Postage Stamps will be received for the fractional part of a dollar, and in any amount when it is impossible for patrons to procure bills, but you must send one or two-cent stamps only.

SUBSCRIPTIONS.—The AMERICAN ANALYST will be sent one year to any subscriber for ONE DOLLAR. New subscriptions can begin at any time.

We Stop the Paper at the expiration of the time paid for unless a renewal of subscription is received. Those whose subscriptions have expired must not expect to continue to receive the paper unless they send the money to pay for it.

Change of Address.—Subscribers wishing their addresses changed must invariably give their former as well as new address.

Missing Numbers.—It occasionally happens that numbers of our paper sent to subscribers are lost or stolen in the mails. In case you do not receive any number when due, write us a postal card and we will cheerfully forward a duplicate of the missing number.

Most Important of All.—In every letter that you write us, never fail to give your full address, plainly written—name, post-office, County and State.

Address all letters to

THE LATEST WHIM.

The latest fashionable "fad" is said to be the ostentatious display in public by fashionable mothers of a tender interest in their offspring. There has been with this class a long succession of favorites, and the period of change in each was that on which the fashion became so general that those who followed it were no longer distinguished from the common herd. Among the different varieties of the canine family each had its turn. The spitz, the poodle, the spaniel, the terrier and the ugly pug have been fondly cherished, provided with a nursery handsomely furnished, fed upon the daintiest viands, washed and perfumed, and bedecked with ribbons and jeweled collars, fondled and kissed and taken to ride in the lap of their mistress, and treated with the utmost tenderness and devotion. At last one of the patronesses of society in search of a new whim hit upon a device likely to captivate all the devotees of fashion. She had a lovely boy whose hair would curl without papers, and she put him on the pedestal for worship. If she wished to decline an invitation to lunch or to a card party, the new-found excuse was a fear that her darling was not quite so well, and she could not leave him. If the servant took him out for a walk, the mother must go close by his side, and manifest her interest and tenderness by a multitude of loving caresses that marked almost every step of the way. In the carriage he supplanted the harnessed pug, sitting in his mother's lap or by her side, and absorbing her closest attention. Her whole soul, judging by the outward manifestations, was wrapped up in her darling boy, and she had eyes and ears and smiles for nothing else. The fashion is taking rapidly, and motherhood is apparently the one absorbing thought. The gay woman of the world, who in the height of the season scarcely looked on the faces of her children from morning to night, has suddenly become absorbed in the care of the sweet darlings, and professes to devote her whole time and attention to their nurture. It is said that the nurse claims that her duties are rendered far more arduous in homes where the new fashion prevails. In addition to the ordinary care she has taken of her charge, she must now have them always ready at an instant's warning for a show parade. Intimate friends are invited to the nursery, into which the fond mother rushes when the names of the visitors are announced, and where she poses as the indefatigable caretaker of the little brood. Or, if the caller is not entitled to such intimacy, the hostess excuses herself as engaged in looking after her household pets, or takes them with her to the reception room as her inseparable companions. Those who have been admitted behind the scenes seem a little uncertain whether the children have lost or gained by this change in the habits of the mother. A dog of whatever species was usually rendered worthless by being so carefully petted, and the transfer of the same attention and manifestation from a similar motive to a child of the family is not, as a rule, a blessing to the new-made pet. The prospect is good for the introduction in time of a new breed of puppies more insufferable than their predecessors in domestic popularity, the pug and poodle.

A WOMAN'S LODGING HOUSE.

At a meeting on June 2d of the Ladies' Health Protective Association in this city, the Secretary, Mrs. Sarah C. Ostram, described a new institution, whose character and purpose will commend it to all who learn of its existence. The speaker designated it as "the only non-charitable cheap lodging house for women alone in the whole city of New York." This interesting establishment is at No. 6 Rivington Street. The building is new, fire-proof, and planned according to the best modern ideas. Its owner is a wealthy woman who refuses to divulge her name. The whole house is "as neat as wax ;" "anybody could occupy it," to use Mrs. Ostram's language. For fifteen cents a woman can secure a clean comfortable bed in a large, neat, well-kept dormitory. This sum entitles her also to the use of a small cupboard, in which she may lock up her effects. Twenty cents are charged for some of the more desirably situated beds in the dormitory—for instance, those nearest windows. The sum of thirty cents buys for one night the use of a sma'l room with one window. Inside rooms cost twenty-five cents per night. There is a pleasant sitting and reading room in the house where the women may read or sew. Several daily papers are provided for them, and an attempt was made, when the house was first started, to furnish them with books and magazines, but it had to be abandoned, because the literature vanished mysteriously. All needed facilities for washing and ironing clothes are supplied, but only a few women care to wash their clothes, and of these few only a small portion care to iron them. The only restriction placed upon the inmates is that they are prohibited from talking after they go to bed. Adjoining the lodging house is a restaurant, where for ten cents a breakfast can be had, consisting of a cup of coffee and a roll or two doughnuts, and a plate of hash or a stew. Women who wish to help their unfortunate sisters can procure at the house cards which they can give to applicants, who will then be cared for as may be directed upon the card.

THE NEW YORK ELEVATOR.

One of the marked characteristics of metropolitan development is the increased value that has been imparted to real estate by the use of the elevator. The city's expansion during the past decade has been vertical rather than lateral—to the obvious advantage of the community, socially as well as commercially. A recent issue of the *Pall Mall Gazette* says : "The overcrowding of London is one of the problems which fill philanthropists with despair. All efforts to surmount the difficulty by planting the people out in the country fail to do more than palliate the evil. Men and women must live near their work, and the result is that, despite all cheap trains, cheap trams and other contrivances for enabling Londoners to live in the suburbs, a densely packed population crowds our streets. Yet crowded as London is, there would be no difficulty in putting up on the same area as that occupied by the metropolis double the population if London were to be built upon principles which prevail in almost any of the large cities in America. London sprawls in unsightly fashion over twice the acreage that is necessary to accommodate her millions. London might be made twice as habitable as it is at present if we built high houses in place of the existing two-story cottages which lumber up so much available building space. The difficulty in the way is that in these high houses there is 'such a getting up-stairs;' and the Londoner has a strong objection to going up more stairs than he can help. This reluctance can only be overcome by providing him with

the means of ascending a high building as easily as he can step into the ground floor. In other words, London can be rebuilt upon its present area under more healthy conditions, so as to afford its denizens far more light and air and the amenities of life, provided the new London can be universally fitted with lifts. The lift, or elevator, is the key to the housing of the poor. The elevator is the answer of science to the bitter cry of outcast London." A moment's thought will suggest the influence that elevators have exerted in real estate values in a city hampered with the physical limitations that attach to New York. Elevators in five buildings in this city transport daily 67,000 people. More people are carried upon elevators in New York in a year than travel in a year over the underground railway in London. In New York the higher the building the higher the rent, so that rents have been directly influenced by elevators. The maximum speed of elevators in England is 300 feet a minute, while in New York 450 feet a minute is not uncommon. In London the elevator service is practically subservient to the staircase. Here the staircase in the high buildings is only incidental. The *British Architect* handles the subject without gloves. "The essential difference," it says, "at present existing between what we call buildings here and those which really are so in America is that the Americans have fully grasped the idea of the importance to the business man of getting quickly to his destination without the worry and exhaustion of personal physical exertion. They have realized, after their usual practical fashion, the unpleasant condition in which such a man is likely to find himself after toiling up four or five flights of stairs, and they have provided against the evil by giving him a quick, comfortable mode of ascent and descent. Not so in England, however. We still cling to our stairs and low-rented top stories as a national institution."

POISONS.

A POPULAR EXPLANATION FROM A SCIENTIFIC SOURCE.

In a lecture delivered March 16th, before the London Institution, on the subject of "What is a Poison," by Dr. Meymott Tidy, the learned speaker said that toxicology is the science of poisons. How comes it to be called toxicology? The Greek word from which it was derived meant a bow, and was used to signify not only the bow but also the arrows used with it. Dioscorides, in the first century, first used the term in connection with poison, which was at that time associated with the art of smearing the arrow heads used in warfare. Thus the meaning of the word tended to enlarge itself, trying, as words do, to keep pace with scientific progress. In that Greek word *toxon* was to be found not only the derivation but the early history of poisoning. A grim interest gathers round the history of poisoning. No doubt the first poison employed was that obtained from the snake. The subtle serpent first taught the art to man, but in those early days it was used in open warfare. But man grows wiser, and perhaps wickeder, and it was reserved for later times to taint the cup of friendship with the deadly venom. Was the suggestion too wild that if it had not been for the invention of more effective means of slaughter, the chemist would still have been called in to aid in the art of poisoning weapons? But if he had missed his chance in that respect, he could still look back to the early days of toxicology as the cradle of science. This art of poisoning arrows went back to quite pre-historic times. Mythological legends tell how Hercules dipped his arrows in poison to slay the Hydra, and how his jealous wife clothed him with the coat of Nessus, wherewith she vainly hoped to regain his affection, but only occasioned the sufferings which destroyed him. Strange it is to note how old is the knowledge of the poisonous nature of putrid blood, and of putrid animal fluids generally. This was recognized in very early times. The blood of a red-haired woman was regarded as especially poisonous. And up to almost recent times blood itself was thought to be poisonous. A king of Egypt was said to have been killed by drinking bullock's blood, and not more than a century and a half ago Blumenbach induced one of his students to drink the same, while he and his class stood by to watch the symptoms. The stories of Circe and Medea, of Drusilla and Locusta, of Tiberius and Nero, of Toffana and the Medicis, were tempting, but were not the subject of the lecture. He had to deal with the question, "What is a poison?" The law has not defined it, but the law frequently demands a definition from scientific witnesses. The popular definitions of a poison are none of them sound, much less scientific. He had searched every dictionary he could put his hands on and believed that the definition in every case amounted to this: That a poison is a drug which kills rapidly when administered in small quantities. But many poisons do neither the one nor the other. The terms "small quantity" and "rapidly" were about as definite as the classical piece of chalk. "Here," said the lecturer, holding up bottles containing nearly an ounce of each, "are oxalic acid and sugar of lead, in about the quantities necessary to be taken to make sure of a fatal result. But we should hardly call these small quantities. And yet these are certainly poisons. Moreover, many of the most certain poisons are very slow in their action. Dr. Tidy defined a poison as "any substance, otherwise than by the aid of heat or electricity, is capable of destroying life by chemical action on the tissues or by physiological action on the organs of the body. There's a good lot of it," he added, "but I can't get it into fewer words." Of course, he explained, mechanical means were excluded. You might kill yourself by swallowing pins, but pins were not poison. Nor is a substance a poison which destroys life by merely blocking out that which maintains life. Then he took two glass jars, one containing carbonic acid gas and the other nitrogen, and dipping a taper in each, showed that it was easily extinguished. "So would you go out," he said, "if you were introduced into either atmosphere. But the nitrogen is not a poison. With 20 per cent. of oxygen in it you can live quite easily; but neither 20 nor 40 nor 60 per cent. of oxygen would enable you to live in an atmosphere of carbonic acid gas, which is a poison." He proceeded to say that nature hates classification, but he must give illustrations of three classes of poison. First, he alluded to sulphuric acid, and showed a part of a stomach charred by the action of this poison. A caseful of stomach and other tissues was shown, illustrating the effects of various poisons, but time did not allow of these being explained. The charring effect of sulphuric acid was explained by the familiar experiment of pouring sulphuric acid on a thick solution of sugar, showing that the effect of the oil of vitriol was to abstract the water, and thus to cause the "charring." The stomach dies. That is molecular death, and this death soon extends to the rest of the body. Carbonic oxide furnished an illustration of a second class of poisoning. A bottle of this gas was lighted at the neck, and burned with a blue flame, "the same as that which you see just over your fire stoves. This gas is always present in coal gas to the amount of 5 or 6 or 7 per cent., and gives it its poisonous character. I don't think carbureted hydrogen burning in the gas jet is at all poisonous. I think all the poison is in the 5 or 6 per cent. of carbonic oxide. How does it destroy life? In this way: The active agent of our blood is the red coloring matter called hæmoglobin. This substance abounds in wonder. I think it is the most marvellous compound, chemically, with which we are acquainted. To live and thrive and flourish we must get albumen and albumenoids. We cannot form these ourselves, but the plant can. The power of building up albumenoid substances is limited to the plant laboratory. Man has the power to change one albumen into another. He can convert albumen into peptone, for example; he can break them up into albumen lower in the scale; but he cannot go higher—*with one exception.* That exception is hæmoglobin, the red coloring matter of the blood. This hæmoglobin, which comes on the scene through a stage opening of which we know not the whereabouts, has a strange property. As a rule, substances which combine with oxygen with the greatest difficulty can be separated from it with the greatest ease; and, conversely, substances which combine with it with great ease can be separated from it only with the greatest difficulty. Gold is one of the most difficultly oxidizable of bodies, and its oxide is most easily reducible. Potassium and sodium, on the other hand, combine with oxygen with the greatest ease, but it required the genius of a Humphrey Davy to separate them. Hæmoglobin is an exception in this respect also. It combines with and separates from oxygen with equal facility. The life of man depends on the perfection with which hæmoglobin performs its function as oxygen receiver, oxygen carrier and oxygen deliverer. But when a man takes carbonic oxide, hæmoglobin combines with this almost as easily as it does with oxygen, and, having taken it, the carriage is full; it cannot take up any oxygen. But, worse than that, it cannot get rid of the carbonic oxide; the carrier cannot unload. In scientific phraseology, the combination of hæmoglobin and carbonic oxide is a comparatively stable compound. The man dies because the sequence of oxidation is interrupted. "Strychnine was the third illustrative poison introduced. This poison was said to destroy life by physiological action. "And what do I mean," said the lecturer, "by physiological action? I mean just simply that I don't know what I mean. Not knowing how it acts, I use the phrase physiological action to conceal my ignorance. It would never do to say we did not know how drugs act, so we say it is a physiological action. But we know one thing about the action of strychnine. We can tell by means of the spectroscope that the fits resulting from the administration of strychnine coincide exactly with the abstraction of oxygen from its compound with hæmoglobin. Why it kills we do not know, and let me remark that it is one of the highest forms of knowledge to know exactly the limits of our knowledge. In fact, the term physiological action no more explains death by poisoning than the term catalysis explains fermentation." But can chemical investigation throw no light on the reason for the poisonous character of certain elements and certain compounds? Given that we know many facts about phosphorus for example—its atomic weight, its relations to the periodic law, its spectrum, and so on—ought we not to be able to foretell, in some degree, its action? This subject was studied first by Blake in 1841, and afterward by Rabuteau in 1867, and by other investigators. At first it was thought that the physiological activity of the elements increased the ratio of their atomic weights, but it was afterward noted that the reverse was the case in certain groups, and the end of the researches was the conclusion that neither in regard to elements nor compounds could any reliable rule be formulated. In inquiring into this subject further difficulties occur in the strange allotropic forms of certain elements and the isomerism of the organic compounds. Illustrations of these conditions were adduced in yellow and red phosphorus, the first of which, the lecturer said, would be fatal in 2-grain doses, while of the other an ounce might be taken without injury, as far as he knew. Ozone was another mysterious body. Every one knows that oxygen is the great life-preserver and life-sustainer. Ozone is oxygen in which three atoms are condensed into each molecule instead of two. But if you put a frog into ozone, into this condensed oxygen, it will soon close its eyes, its respiration will fall rapidly, and it will die simply for want of oxygen. As an illustration of isomeric bodies take these two substances, morphia and piperine, send them to a chemist for analysis, and his report will be that they are identical in composition; and yet the one is of all things in the world that which is most calculated to send one to sleep, and the other is of all things in

the world the compound to keep you awake. In ancient times the arts of witchcraft, medicine and poisoning were bound up together. The Greek word pharmakist was used to signify dispenser of medicines, a witch and a poisoner. One of the great services that science has rendered to mankind has been to separate these notions. The modern pharmacist no longer requires the stuffed crocodile to watch over his incantations, to aid in the composition of his medicines. And science has done more than this. It has rendered impossible the secret vilainies of the old poisoners. It follows the traces of secret treachery with a bloodhound scent, and will ultimately tend to repress entirely the crime of poisoning.

TONS OF CURRENCY.

COUNTING THE MONEY IN UNCLE SAM'S TREASURY.

The new treasurer of the United States has only recently finished counting out his money. It took some time, because it is no small job to reckon over 4,500 tons of coins; and this is apart from $300,000,000 or so in bank and treasury notes. For several weeks clerks were engaged in clinking the gold and silver which fill Uncle Sam's huge cash boxes, telling over the shining pieces, weighing them out and sealing them up in bags. One gets a notion of the magnitude of the task when it is considered that one of the vaults beneath the ground floor of the national treasure house, containing 85,000,000 silver dollars, is 100 feet long, 60 feet wide and 14 feet high—chock-full of coined precious metal. As you walk around this huge lattice-work box of iron and view its dimensions, you begin to realize the actual magnitude of so vast a sum. To empty the receptacle with a coal shovel would require many months of hard labor, if you had to do the work unaided. When the great French actress, Rachel, who had always been very poor, was suddenly placed in possession of a large heap of gold coins, she put them into a basin and poured them over her bare arms delightedly, with ecstatic enjoyment of a literal wash in wealth. You might fairly swim in gold and silver in these immense coffers at the treasury. There is another which contains $25,000,000 in gold and $60,000,000 of silver also. In counting these masses of silver and gold, each bag containing $1,000 is removed from the vault and first examined to see if the seal is intact. If so, it is placed upon scales and weighed. On one side of the balance are put one thousand unused dollars, and the sack must be found an equal counterpoise. Supposing that it is light, it is opened and the money in it is reckoned piece by piece. Coin suffers more or less loss of weight by abrasion, even when not in circulation, and it might be that a bag would be less heavy on this account, though having in it the required $1,000. Also when a seal has been disturbed the contents of the sack are poured out, stacked up, counted and put back again. The sacks which are opened are resealed; but ordinarily the seals are found all right and the weight is correct, in which case the bags are computed as representing so many thousands, and no further trouble is taken with any of them before putting them back into the vaults. When the gold is gone over, a particularly rigid inspection is exercised by the overseeing officials, because the value is so much the greater. It is a very interesting sight to watch the millions in paper money—bank notes, treasury notes and gold and silver certificates—being counted by deft-fingered young women in a big room beneath the treasurer's office. Every dollar has to be numbered before the new guardian of the national cash-box gives his receipt in full to the new out-going incumbent. The stuff is all kept, save such small change as is needed to transact Government business with, in the shape of packages, each about one foot cube, which are stored away on shelves in vaults. Cash in the shape of gold or silver takes up a great deal of room, but in bills enormous sums require very little space to hold them. One of the vaults, which is nothing more than a big safe about as large as an extra-size closet, alone contains $150,000,000. Each package holds four thousand notes, is done up in ordinary brown paper, and labelled on the outside in red figures with the amount enclosed. If it is a parcel of twenties, the bundle represents $80,000; if hundreds, $400,000. Just such a package was made up a few years ago that held $40,000,000 in gold certificates of $10,000 each. You could carry one like it under your arm very comfortably. The packages of notes are brought down on little trucks by the elevator from upstairs and wheeled into the room where the counting is done. They are brought by the assistant cashier in person, and the committee in charge of the reckoning receipts for every bundle. Each parcel is opened in its turn and the contents handed over to one of the skilled young women, who is responsible for it, and signs a guarantee of its correctness before it leaves her hands. She runs over the crisp, unused bills with fingers marvellously rapid, taking note not only as to whether there are four thousand of them enclosed, but also regarding the numbers on the notes themselves, which must run in regular order. If there is a number wrong, her practiced eye detects it swiftly; or, if a bill is defective in its printing, she removes it, and it is sent back to the Bureau of Engraving and Printing, to be replaced with another. When the bundle has thus been found correct, the notes are put under a hand-press for a moment to reduce them to the least possible bulk, a new wrapper of brown paper is put around them, and a seal with red wax completes the operation, at the conclusion of which a memorandum is made of the sum the package contains, and it is ready to be sent back to the vaults with its fellows. At the close of the last count that was made of the money in the treasury the cash was found $19 short, but the amount was subsequently swept out of the corners of one of the vaults in the shape of some stray silver coins. It is said that no deficiency of this sort has ever occurred save once, when the specie turned over to a new treasurer proved to be just three cents short, and the out-going official was obliged to make up the amount out of his own pocket. If it should ever happen that an unexpected hole in the assets was made by an embezzlement or otherwise, the treasurer would be responsible, but Congress would undoubtedly make it up for him by a special appropriation. It is hardly likely that such a thing can occur, however, inasmuch as things at the treasury are so arranged that not even the treasurer himself can possibly steal a dollar, nor yet the secretary of the treasury, nor the register, nor the cashier, nor anyone else, unless a conspiracy were organized. Furthermore, if anybody succeeded in breaking in from the outside, he could not very well get away with more than two hundred pounds of gold, which only represents about $50,000. A million dollars worth of that metal weighs one ton. This would be discouraging. Not long ago there were certain treasures of considerable value in the treasury, in the shape of articles made of gold and silver and precious stones, which had to be looked over and receipted for, as well as the money. Most of these things were presents which had been made to the various Presidents of the United States and to other officers of the Government by foreign powers and potentates, and which they could not accept on account of the existing law forbidding the reception of such favors. Among them was a bottle of attar of roses, given to President Grant by the imaum of Muscat, which held a pint of this valuable fluid; also a bottle of pearls, another bottle of diamonds, a gold sword scabbard, a diamond snuff-box, ten beautiful sabres from Ali Pacha, bey of Egypt, and lots of other such trifles. In old times the patent office was a sort of museum of curiosities, and these gifts and other valuables were deposited there. A large part of them were stolen twice, and on the occasion of the second robbery the thieves got away with pretty nearly all of them that were worth taking. They secured the bottle of pearls and the bottle of diamonds, as well as the diamond snuff-box, the scabbard of the gold sword and a number of medals Not even the pint bottle of attar of roses did they leave behind. This disaster occurred on the night of November 9, 1848, and on the following day a reward of $1,500 was offered for the capture of the goods and the burglars. The latter were traced to New York, where the treasures were recovered, although the precious articles of gold and silver had been melted down, after removing the gems with which they were set for pawning separately. Later on it was thought desirable to hand over the whole business to the care of the treasury, which was done in 1883. The collection remained in its hands for some years, until a while ago it was turned over to the National Museum. There were some curiosities among these valuables which are rather difficult to account for—for example, two Rio de la Plata dollars, a shotgun with gold mountings, seven gold coins from ancient Rome, a pair of pistols and a pearl necklace, There were ever so many medals of all sorts, in gold and silver. One box there was full of diamonds and pearls, which had been presented by the emperor of Japan to President Monroe. The gems were not of the very finest kind, being intended for the decoration of sword-hilts and purposes of that sort, but nevertheless they were worth a good deal of money. For years that box of jewels gave great annoyance to the officials at the treasury. Every time there was a count of the assets of that institution, President Monroe's casket would turn up, and eager Washington correspondents, with noses preternaturally alert for news would send out all over the country reports of the discovery in an odd corner of an unswept vault, of a box full of precious stones belonging to the family of Mr. Monroe. Whereupon, editorials would appear in papers opposed to the administration, condemning this neglect and demanding that the treasure be turned over to the indigent descendants of the author of the famous doctrine. Between whiles, charges would be printed to the effect that the pearls and diamonds in question, having been unheard of for some time, had presumably been distributed among the heelers of the wicked party in power. Congress never passed an act permitting Mr. Monroe to accept the gift in question, and so it was transferred to the National Museum, together with the rest. There were other valuables also given into the hands of the treasury which were captured and confiscated during the war. Among them were 240 watches, eighty-five chains, eleven rings, six lockets, one bracelet and one pair of compasses. Most of these were secured at one haul from the person of a Southern banker, with whom they had been deposited for safe keeping, He fled with them on his person, and was so unfortunate as to be caught. For a long time there were large stories current of the wealth in the possession of the Government got during the Rebellion. It was told how the ladies of Richmond, inspired by noble and patriotic motives, turned their jewels, watches and money into the Confederate treasury, piling up a vast amount of value there, and how the "swag," as vulgar burglars phrase it, was gobbled by the Union forces. But the fact was that the latter found no treasures of any sort to gobble in Richmond, and the heaps of riches in cash and collateral referred to were all imaginary.

LUMINOUS CRAYONS.—A luminous crayon has recently been invented to enable lecturers to draw on the blackboard when the room is darkened for the use of the lantern.

BLIND ECONOMY.—There is danger in going to the low-priced, cheap plumber to get work. It may not always be the case, but in most instances the low-priced man is a poor workman and a skinner. No one can have poor plumbing done at any price; he cannot afford to have it put in for nothing. There is economy in having good work done besides the security it affords in the matter of health. Pay a good plumber a good price and get good work should be the rule.—*Sanitary News.*

ARTIFICIAL COFFEE.

A SWEDISH SWINDLE, WITH HEAD-QUARTERS IN PHILADELPHIA.

"Lactoserin!" What is it? 'Tis an imitation of coffee—an excellent imitation, too—and it comes from Sweden. It looks like coffee and smells like coffee, but it isn't coffee, and consumers will, in the future, do well to look to what they are buying, as otherwise they may be made the victim of a remunerative Swedish "joke"—remunerative to the gentlemanly perpetrator in Sweden. The difference between genuine coffee and its Swedish imitation is very pronounced when the test is applied—the test of taste. The imitation looks like the genuine article, but does not taste like it. As soon as it is cracked by the teeth it resolves itself into small particles in the mouth. With a view to finding out something about the imitation, a reporter for the *Blade* called on Mr. Woolson, of the Woolson Spice Company, last evening, and asked him regarding it. "We have received several communications and samples of the 'coffee,'" said he, "but have paid no attention to them. The 'imitation' is, of course, a fraud—*i. e.*, so far as it being equal to genuine coffee is concerned—and it may for a little time interfere in some degree with the legitimate coffee trade. One of our men last week visited a regular customer and asked, as usual, for an order. The dealer told him he had bought coffee cheaper elsewhere and had made more money on it than he could on ours. Our agent wanted to see the coffee. After examining the package produced, and finding the contents to be a mixture, he purchased it, and here it is." The inventor of the "new coffee," Wm. Rehnstrom, of Stockholm, Sweden, some days ago wrote a letter, it is learned, to the Dowling Manufacturing Company of Philadelphia, in which he says he is glad his invention is getting on so well in the United States, and in which he declares it to be a merchandise just as good as it is valuable. He adds that by adding Lactoserin to coffee "we have values in millions. The production of coffee is limited—of Lactoserin unlimited, or the less coffee, add the more Lactoserin." The Dowling Manufacturing Company have a corner on the new merchandise, and are flooding the country with sample packages, and with each of which goes a letter announcing that their long negotiations with the representatives of Mr. William Rehnstrom, of Stockholm, Sweden, have been successfully concluded, and that henceforth the exclusive use in the United States rests with them for "Lactoserin" for and in combination with coffee. Here Mr. Woolson emptied the contents of the package on the table and leveled the pile. He then placed his hand on it, and raised it quickly. "You see," said he, with a smile of triumph, "that the genuine coffee of the mixture will stick to the palm, the imitation won't. They cannot put the gloss on the bogus article that beautifies the genuine." "Is the gloss put on coffee during the process of roasting it or afterwards?" "Afterwards. But to go on about 'Lactoserin,' it may be said that it is liable to become a dangerous article in the coffee trade unless steps are taken to regulate it. I do not think it can be suppressed at once, as its inventor, William Rehnstrom, of Stockholm, Sweden, has patents on it in this country. The berry of the imitation, you see, is much heavier than the genuine, but it lacks the gloss, and the crease is not like that of nature's production. The imitation will be manufactured at 10 cents per pound. A half pound of coffee at 25 cents and a half of 'Lactoserin' at 10 would make a pound of mixture worth 17½ cents. It would sell readily at 25 cents, as the people know nothing of the new article, and have been paying 27 cents a pound. and the profit to the seller would be 9½ cents. This is quite an item, when it is taken into consideration that there is very little, if anything, made on coffee by the retail dealer. The genuine article costs him 25⅞, and he grinds and sells it for 27. The temptation to make something will probably prove so strong that a good deal of 'Lactoserin' will be sold. In ground coffee it cannot easily be detected, as it has the color and odor of the genuine." "What do you think 'Lactoserin' is made of, Mr. Woolson?" "Probably musty flour, though I do not know. If it is made of flour, it is not dangerous, but it cannot be determined what its ingredients are. It may be a kind of clay." —*Toledo Blade.*

METHEGLIN AND MEAD.

ENGLISH BEVERAGES MADE OF HONEY.

As such large quantities of honey are now imported from North and South America and the West India Islands, besides our home productions (2,000 to 3,000 tons), it may perhaps be useful to give a few recipes for utilizing honey in some of our popular drinks. Our imports have averaged for the last four years 900 tons per annum. In food substances sugar has chiefly superseded honey. The subject of sparkling wine has already been discussed in previous volumes of the *Review*, in 1887 and 1888, but a little new matter on the subject may be added. The earliest manufactured kind of intoxicating liquid was probably mead. From honey a fermented beverage is made, which is largely used throughout the Soudan. Mead is said to have been the principal beverage of the Britons before the use of malt liquors among them; and long after the introduction of the latter beverages mead was a favorite drink. Under the name of metheglin it was frequently alluded to by old writers. Mead formed the ancient, and for centuries the favorite beverage of the northern nations. It is still called by the Germans honey-wine. Mead is frequently mentioned by Ossian. Dryden has a couplet:

"T'allay the strength and hardness of the wine,
Let with old Bacchus new Metheglin join."

Queen Elizabeth was so fond of mead as to have had it made for her every year. Mead formed the nectar of the Scandinavian nations, and was celebrated by their bards; it was the drink which they expected to quaff in heaven out of the skulls of their enemies, and was, as might be expected, liberally patronized on earth. The Scandinavian mead is flavored with primrose blossoms. In Spain mead is known as aloja. The Africans use several honey drinks, hives being common. In Madagascar they make a honey wine, a composition of three parts of water to one of honey, which they boil together and skim after it is reduced to three-fourths. They afterwards put it to ferment in large pots of black earth. This wine has a pleasant tartish taste, but is too luscious. In Abyssinia, according to Bruce, they use five or six quarts of water to one of honey. These they mix together in a jar, throw in a handful of parched barley meal and some chips of a bitter bark, which, in a few days, takes off the cloying taste of the honey and makes the beverage wholesome and palatable. Braggon, or Bragget, was a sort of metheglin. Hydromel is honey and water submitted to fermentation. Oxymel is a mixture of honey and vinegar. Here is a more modern recipe than Queen Elizabeth's for mead: 8 ozs. each of sarsaparilla, liquorice root, ginger, and cassia bark, 2 oz. of cloves and 3 oz. of coriander, suitably cut and bruised, are boiled for 15 minutes in 8 gals. of water, allowed to cool and settle, and then strained through flannel. To this is added in the fountain 1½ gall. syrup, ½ gall. honey, 4 ozs. each of tincture of ginger and solution of citric acid, and afterwards sufficient water to make 10 galls., when it is charged with carbonic acid gas. The following recipe for metheglin was published in the *Journal of Horticulture* by a Mr. J. Oliver, of Hartington, Derbyshire: When the comb has been drained of the honey, put it in a large vessel, then pour in sufficient lukewarm water to swim it nicely; let it stand two days, stir it occasionally, then strain it; skim the scum from the liquor carefully, filter the sediment through a flannel bag, then boil one hour. To 3 galls. add 2 lbs. of raisins, 1 oz. of ground ginger, and 7 or 8 laurel leaves, then cool. Add a little of brewers' barm, let it stand part of a day, then barrel it, leaving the barrel open for two or three days; then bung it up, and let it remain untouched for six months, then bottle it. I dare say some who try their hands at making this honey drink will be anxious to taste it before the expiration of the six months, but the longer it is kept the better it will be. If an egg will float on the liquor it will be about the right strength. Metheglin may of course be made from pure honey, but by soaking the combs in water we utilize the honey which would otherwise be lost. A little lump sugar put in each bottle will make it as fine as brandy.

Honey Wine is made of the juice of the best grapes, well ripened, and kept twenty days before pressing, to which five parts of the finest honey should be added, and all well stirred in a wooden vessel. Cover with a linen cloth, and allow to ferment for forty days, the scum being occasionally removed. It is then put in a light cask, and so kept till the ensuing spring, when it is bottled. The Jews in Morocco are very fond of Mahaya, a weak, colorless spirit, flavored with aniseed, which they prepare from water in which honeycombs have been boiled. The distillation of this spirit is conducted in the rudest manner. Dr. Leared in his work, "Morocco and the Moors," states having witnessed the process. The condenser consisted of an old gun-barrel, while the water into which the lower end was plunged, in order to cause condensation, was allowed to become too hot for the hand to bear.

Honey Currant Wine.—To 3 qts. of juice add 3 lbs. of honey and water to make a gallon; let it ferment four or five weeks with open bung, and keep the barrel always full, in a warm place; then drain and put into another barrel in the cellar. It makes a delicious drink.

Honey Noyeau.—4 ozs. of bitter almonds, 2 ozs. of sweet almonds, 2 lbs. of loaf sugar, 3 lemons, 2 qts. of gin, 2 large spoonfuls of clarified honey and 1 pint of milk. Blanch and pound the almonds, and mix them with the sugar, which should be rolled. Boil the milk, and when cold mix all the ingredients together, and let them stand ten days, shaking them every day. Filter the mixture through blotting paper, bottle off for use, and seal the corks down.

Cheap Harvest Drink.—To those engaged in harvesting and other occupations tending to create thirst, the following preparation may be recommended, which makes a very palatable and healthful drink in hot weather: Take 12 galls. of water, 20 lbs. of honey, and 6 eggs, using the whites only. Let these boil one hour, then add cinnamon, ginger, cloves, mace, and a little rosemary. When cold add one spoonful of yeast from the brewer; stir it well, and in twenty-four hours it will be good.—*London Mineral Water Trade Review.*

CARATS.

THE STANDARD OF FINENESS FOR GOLD AND DIAMONDS.

The word "carat" comes from the Abyssinian name for bean. It corresponds in weight with a certain species of East India bean, and was originally used only as a weight, in the same manner as our word "grain" comes from a grain of wheat, and has also its average weight. The exact relation of the carat to the grain. Troy weight, is, in round numbers, as 4.608 to 1.185; or, in other words, 1.185 carats are equal to 4.608 grains Troy. By division of the last number by the first we find for the weight of a carat 3.88 grains very nearly. The carat is the weight by which jewelers sell diamonds. The carat is now only used for weighing precious stones and pearls, because the grain is too small. In ancient times it was used as the unit of weight for gold, but it is now, on account of the greater abundance of that precious metal, superseded by the ounce. In regard to the alloy of gold, it has been accepted to take 24 carats of gold or 93 grains, very near, as the standard of pure gold, and to call gold in which 20

carats in 24 carats are pure gold, gold of 20 carats ; when three-fourths is pure, or 18 carats in 24 carats, it is called 18-carat gold. So, in regard to the alloy of gold, the word carat has become similar to the expression of a percentage, with the difference that 24 is substituted for 100. So 18-carat gold is identical to 75 per cent. fine ; 12-carat to 50 per cent. fine, etc. That this manner of estimating the value is kept up is simply due to the custom of following the duodecimal system in making alloys, which naturally drives us to the expressions 70, 80, or 90 per cent., when speaking of the fineness of the most valuable metals.

DOMESTIC DIETETICS.

SPECIALLY PREPARED, FROM PRACTICAL TESTS, FOR THE LADY READERS OF THE "AMERICAN ANALYST."

SEASONABLE FOOD.

June.

MEAT.—Beef, lamb, mutton, ham, kidneys, liver, sausage, veal.

GAME AND POULTRY.—Pigeon, chicken, duck.

FISH.—Anchovy, bass, bluefish, blackfish, cod, eels, clams, flounder, haddock, halibut, herring, lobsters, mackerel, mussels, perch, porgie, prawn, salmon, shad, turtle, trout, sturgeon, whiting, weak-fish.

VEGETABLES.— Beans, cucumbers, carrots, cauliflower, lettuce, onions, parsley, parsnips, potatoes, shallots, spinach, turnips, radish, rhubarb.

FRUITS.— Cherries, strawberries., bananas, pineapples.

PRACTICAL RECIPES.

MEAT RISSOLES.—Take equal portions of tongue, ham and chicken or veal, and mince them up, season highly, adding a little cayenne pepper and a little lemon juice ; bind together with a beaten egg ; take off little pieces the size of a small walnut and lay them in little pieces of very thin paste ; fold over the edges and flatten them down, keeping the rissole as round as possible; dip them in egg and crumbs, and fry a nice brown in boiling lard.

PORTUGUESE SOUP.—Slice an onion into a pan and fry it in a piece of dripping the size of an egg ; add salt and pepper, and water enough to make a quart ; let it boil, then strain it and add a bouquet of herbs in which there is mint, and some slices of bread. Boil slowly until it is well flavored, then skim out the herbs and serve.

EGGS COOKED IN GRAVY.—Put some roast beef gravy in a frying-pan and poach your eggs in it. Have ready a heated platter with some slices of buttered toast in it; lay an egg on each slice and pour the gravy over all.

POTATO PANCAKES.—Peel your raw potatoes and grate them, season with salt, add a little flour, two or three eggs, according to the amount of grated potatoes used, and a little milk to make a good mixture ; form into little cakes with the hands, and fry in hot lard.

SARDINES ON TOAST.—Carefully scrape off the skin of the sardines and take out the backbone, sprinkle over them a little red pepper. Pour the oil in which they came into a small frying-pan and put the sardines back in it and allow them to get very hot, then lay them on small thin slices of hot toast and serve at once.

PIE-PLANT SHORT CAKE.—Make a short cake with a quart of flour in which is sifted two teaspoonfuls of baking powder and half a teaspoonful of salt ; rub in a heaping tablespoonful of butter and make the consistency of very soft biscuit dough with sweet milk. Bake in two cakes about three-quarters of an inch thick. When done split, and put a layer of pie-plant, stewed with considerable sugar, between the layers of crust and on top of them.

STRAWBERRY ICE.—Press enough ripe strawberries through a colander to make a quart of juice. To this put a quart of cold water and make it *very* sweet. When you put it in the freezer add the unbeaten whites of three eggs. Freeze and pack.

OLIVE OIL FRAUDS.

THE IMPORTED ARTICLE MADE OF PEANUTS AND SEEDS.

In a recent issue of the San Francisco *Argonaut* a letter was published from a gentleman of that city who, after graduating from the University of California, went to Europe for several years to study all that relates to the culture of the vine and the olive-tree, and the making and treatment of wine and oil, and has been in France and Italy for several years. In view of the growth of those industries in California, the following extract may interest some of our readers :

"MONTPELLIER, FRANCE, *April* 1891.

"One hears so much of the adulteration of almost all articles of daily consumption, that a few words about what I saw in this line may be of interest. While at Marseilles I visited the magnificent docks, and saw thousands of tons of peanuts and other grains from which oil is made. Great iron steamers were unloading heavy cargoes of these grains. Most of it came from Africa or Asia, where slave labor makes their production very cheap. The next day I visited some of the large oil-mills in the outskirts of Marseilles. Here I saw these peanuts, cotton-seeds, colza, sesame, etc., ground up and pressed. It was an interesting sight, I assure you ; but apart from the fine machinery in use, the names on the barrels of oil were of great wonder to me. Afterward, at Nice, the most important oil centre in the world—I found that among all the numberless oil merchants not more than *three* ever sell really pure olive-oil ! Leaving the warehouses and docks, I rode through the beautiful olive-covered country, and was astonished to see so many acres of magnificent olive-trees being cleared and planted in grass. Questioning the men, I found that the price of genuine olive-oil had been so reduced by competition with grain oils under the name of olive-oil, that the poor producers could not pay expenses, and were forced to uproot these grand old trees and plant something that could not be pirated by unscrupulous merchants. In other industries, the law compels every one to sail under his own colors. When the oleomargarine threatened to ruin all the buttermakers of France, the law compelled merchants to 'call a spade a spade.' Recently, plastered wine became omnipresent. The government put an end to plastering—not by forbidding it, but simply by compelling merchants to indicate the nature of the product they offered for sale. Needless to say, no one would buy plastered wine if they knew it as such. The reason that cotton-seed, peanut, etc., oils are allowed to be sold as 'pure olive-oil' is twofold. First, because the oil merchants are united against attempts to interfere with their trade ; second, because, up to very recently, it was almost impossible to detect mixtures of cotton-seed oil, etc., with the pure product of the olive. Recently, however, the much talked of difficulty in detecting falsifications has been sweept away by the discovery of a simple and cheap detective that gives infallible results. The Italians claim that it was Professor E. Bechi, of the royal station of Florence, who first discovered it. The French say that it is due to the labors of Mr. R. Brulé, director of the government station Agronomique de Nice. I do not wish to enter into the controversy. Suffice it to say the two methods differ but little, and great credit is due both gentlemen, for their discoveries were made, I believe, independently. I had occasion to pass several days in the government laboratory at Nice each time I passed through that city, and I made experiments with pure oil and mixtures. I was able to detect unmistakably five per cent. of cotton-seed oil in olive-oil and less than three per cent. of oleomargarine in butter—for it works even more perfectly with butter than with oil. Some day, when you have an hour to spare, you can do all the tests yourself. You need but a solution of nitrate of silver, twenty-five for one thousand in alcohol of wine at ninety-five degrees, a few test-tubes six inches long, and a basin of water kept at boiling point over an alcohol-lamp or stove of some sort. Put in one test-tube pure olive oil ; in another pure cotton-seed oil, and then make any mixture you choose. In each case use twelve cubic centimeters of the oil you wish to test and five cubic centimeters of the reactive. Put the tubes in the bath of boiling water and watch the results. You can do six or eight dozen at a time by numbering your test-tubes. The whole operation lasts but thirty minutes at most. Pure olive-oil, well made, remains clear and of a greenish tint. Cotton-seed oil turns black, and mixtures vary in color. Poorly made oil of the second pressure clouds up at first, but soon regains a greenish color. This test is *infallible*, and once seen never can lead to mistakes. When this discovery was first made known, the oil falsifiers took prompt steps to muzzle the press and buy off all who attempted to make it known generally. They were at first successful ; but, thanks to the outside press and the patient and determined efforts of a few people, the cat got out of the bag, and a great commotion ensued. Buyers of oil now demand Brulé's analysis, sworn to before the consul, before they will accept shipments. I know of one man who is making a great deal of money by offering, as an inducement, Brulé's analysis *free*, thereby proving the old saying that honesty is the best policy. If this crusade against falsifications continues to be as successful as it has been thus far, I have no doubt that the culture of the olive will regain its former importance, and the poor peasants will be once more happy, as they were before cotton-seed and peanuts gained the mastery. The grower of olives in California should be careful to fight the adulterators before they gain too much power. Steps should be taken to establish laboratories where consumers could have analyses made without trouble or expense. The slight cost of such stations would be paid for a hundred-fold by the increase in price of the pure article. Why should not Congress extend the oleomargarine law to oils, and compel various oils to sail under their own flags."

GRAVITATION.

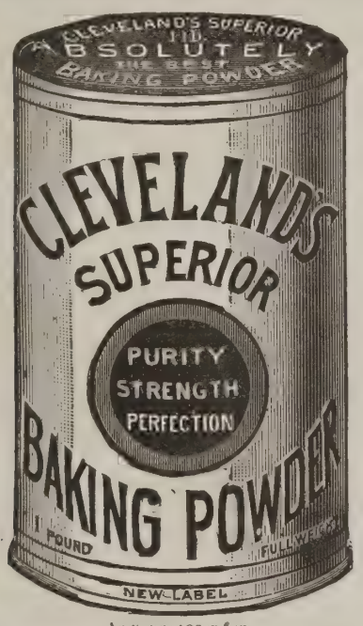
ITS CHARACTER ONE OF THE SUBTLE MYSTERIES OF NATURE.

One of the brightest and most thoroughly informed writers on the staff of the *Electrical Review* of this city conceals his identity under the *nom de plume* of "The Prophet." In the issue of that journal of June 6th he presents the following suggestion relative to the mysterious force which we designate "gravity :"

What is electricity ? This question is often asked, but, strange to say, rarely with a view to obtaining information. It is frequently used as a poser to floor some loquacious person who has been talking glibly of the subject. One who attempts to answer it seriously is looked upon as presumptuous. But we really know more about electricity than we do about gravity. Every day throughout this broad land school children are giving to their teachers what is considered to be the correct answer to the question. What is gravity ? Yet the student who told his professor that he knew what electricity was, but had forgotten, has become the butt of a very trite joke. Of the true nature of the mysterious force of gravity little is known. The recent unparalleled advances in physical science leave us still in the dark as to gravity. It is the same silent, never-ending force which keeps the universe in balance. No

one has ever been able to screen its attractive effect for even one single second. Go where you will, you cannot escape its force. It causes a stone to fall and a balloon to rise. It makes rain, rivers and mountains, but of its exact nature we know infinitely less than we do of electricity. Who has ever heard of a wave of gravity, and who can tell the medium by which its power is transmitted from sun to earth? It has been proved that light and electricity are similar manifestations. Waves of light and electricity are now almost tangible every-day things. Electricity can be generated, propagated and suppressed at will, but gravity goes on, always acting, never changing, and successfully defying the power of man. Many of the actions which are now ascribed to gravity were formerly accounted for in a manner which seemed quite as reasonable as our present explanations. The ordinary suction pump, it is now known depends for its action upon the pressure exerted on a column of water by the air; but in the time of Aristotle it was explained by saying, "Nature abhors a vacuum." It was observed that space seemed always to be filled by matter, and the moment a solid body was removed its place would be filled by air or water. Thus, when the piston of a common pump was lifted, the water was caused to rise, and the explanation was all sufficient. It was not until the seventeenth century that the defect in this theory became apparent. The Duke of Tuscany sunk a very deep well and notwithstanding the skill of his best engineers, the water would not rise in the pump much over thirty feet. Galileo, who was then near the close of his career, was appealed to, but he, after remarking that nature did not abhor a vacuum over ten metres, referred the matter to his ablest pupil, Torricelli. The latter reasoned that if it was the weight of the air which sustained the water, that it ought to sustain a much shorter column of a heavier liquid like mercury. He accordingly inverted a long tube filled with mercury over a pan of that liquid, and found that the mercury fell until it came to rest at a height a little over thirty inches, leaving a vacuum at the top of the tube. This upset the Aristotelian doctrine that nature abhors a vacuum and prepared the way for the law of gravitation. We know many of the laws of gravity, but of the thing itself we know nothing. It may yet be proved that gravity is also an action propagated through the ether. It would thus come under the domain of electricity, which seems destined to absorb all of the sciences. Perhaps, then, when the great secrets of nature are unlocked we may be able to suspend or screen its action at will. This would be a most stupendous triumph of electricity. Until the scoffer can tell what gravity is, let him not ask "What is electricity?"

THE MATRIMONY BUSINESS.



STATISTICS OF A EUROPEAN MATRIMONIAL BUREAU.

One of the noteworthy institutions of the German capital is the Great Berlin Marriage Bureau, which has ramifications all over the world, and which, it is reported, has in the last eleven years received 19 959 propositions from all civilized countries. In 12,706 cases husbands were desired; in 7,253, wives; in 4,916 women and 5,104 men communicated directly with the main office; the rest made known their wants through agencies. The youngest woman who asked for a man was 16 years and 4 months old; the eldest, 72. The corresponding ages of male applicants were 18½ and 79. The average age of the women was 26½; of the men, 29½. Matches were brought about for 4,399 women applicants and 5,417 men. The average fortune of the men was $3,750; of the women, $4,700. The smallest purse offered by a woman applicant was $75. It was the whole fortune of a girl of 21 years. The largest fortune of a woman applicant was $500,000. The properties of the men in search of wives varied between $375 and $150,000. There were 516 women and 307 men who communicated with the bureau who had apparent physical deformities. There were 2,311 and 1,409 women who had been married; 1,129 men wished second wives to take care of first wives' children. The occupations of the men were: Tradesmen, 5,002; members of learned professions and artists, 706; army officers, 93; State officials, 809. The rest of the candidates did not name their occupations. Of the women, 1,503 had their own business establishments. From the time of the offer of marriage to the date of the engagement, the average interval was 41 days. In 219 cases the marriage resulted in a speedy divorce, and 106 of the men and 143 of the women ran away without waiting for a legal separation. In 391 cases the bureau was brought into court in consequence of misunderstandings as to the dowries. These statistics comprise about one-half of the business of Berlin in the negotiation of marriages through agencies. A dozen small concerns devote themselves to the bringing together of matrimonially inclined men and women, mostly of the poorer and lower classes. Till recently, moreover, the big concert hall in the Leipziger Strasse gave every Thursday evening a matrimonial concert to which all mammas with eligible daughters were specially invited. On these evenings all the tables in the first story of the great house were occupied with family parties, whose plump and simpering daughters crochetted or knitted industriously throughout the entertainment, so as to show the eligible young Berliners present how capable they would be at housekeeping. In this musical marriage bureau, middle-class German girls went off like hot cakes; but no attempt was ever made to calculate the average number of engagements per evening, as the whole institution was merely an advertising appendage of a great musical resort. It is certain, however, that an astonishingly large percentage of the houses in Berlin and its immediate vicinity owe their existence to the interposition of the numerous matrimonial bureaus there. The figures most interesting to foreigners, especially to Americans, have unfortunately been omitted from the statement of the Great Berlin Bureau. Every boarding-house keeper knows, and most of them acknowledge it, that speculation in English-speaking women is the most considerable feeder of marriage agencies at the German capital. "Auf Amerikanerinnen wird besonders speculirt" is the familiar phrase which greets every inquirer into this branch of the business. American women travel much alone in Germany, and not a few of them live without the immediate protection of family or chaperons, in the large city boarding-houses. The German man always supposes that such an unprotected and unchaperoned American woman is an orphan with an independent fortune, or something equally good, and does not think long before making heroic efforts to encompass the possession of both heiress and property. Marriage brokers are constantly besieged with requests for introductions to such rich American orphans, particularly from insolent young officers, and it is not unlikely that at least eighty of the ninety-three officers mentioned by the Great Berlin Bureau made known their wants on the condition that only Americans need apply. The game between the agent and the boarding-house keeper is simple. He goes to her with the inquiry whether she has, or will have soon, young American women in her house. The answer is invariably affirmative, for every boarding-house keeper catches an American girl sooner or later. The agent then explains his errand, gives his military customer a gilt-edged title, character, and so on, and agrees to give the woman 33⅓ per cent. of his commission in case their united efforts accomplish the match in question. This commission is regulated according to the size of the American girl's dowry. A case without a dowry is not on record, for a dowry is the *sine qua non* of the whole affair. The housekeeper's duties are simply to find out all about the American girl's property and family, and are, therefore, not onerous, for she would exert herself to get this information for her own private satisfaction anyhow. If this course of inquiry elicit the fact that the American girl is a real American heiress, with real American gold to the amount of a thousand or more annually, the spick and span young officer, with his income of minus a thousand or more annually, is brought round in a whip-stich. He appears at dinner at the landlady's right, and is introduced as Herr Baron Bierfass, of the Guards, best friend of the Imperial Caretaker of the Boots. He is all red-and-blue, with sleek hair parted down the back of his neck, and a mustache pulled out straight to his ears. He talks German love as fast as a dog can trot, and, if he does not get the girl, it is because she does not love an officer of the Guards when she sees him. American mammas and papas are frequently dazzled by the great names in the letters of their daughters in Germany, and they palpitate with modest American pride when "Von Leberwurst" or "Von Schalkopf," with a "Lieutenant Herr Baron" or a "Hauptmann Herr Graf" before it, shines in the list of regular callers. A glance behind the scenes of the Great Berlin Bureau and other similar institutions of the Hohenzollern capital, with their wholesale trade speculation in the trans-Atlantic Nellies and Minnies and Lauras and Florences, would, however, probably in most cases result in the speedy termination of "daughters studying music or the language in Germany."

HEREDITARY TAINTS AND DISEASES.

The Biblical writer who enunciated the superb aphorism, "The fathers have eaten sour grapes and the children's teeth are set on edge," expressed in poetic form one of the greatest of physiologic truths. Parents transmit to their offspring all their physical, mental and moral peculiarities, and also their tendencies towards disease or general ill-health. In most cases the transmission is so complete that the same malady appears in the same form in both generations. This is true of scrofula, epilepsy, St. Vitus' dance, consumption, anemia, rheumatism, hare-lip, baldness, bad teeth, dyspepsia, leprosy and impure blood. In other cases Nature seems to try to alleviate the trouble, and make it less in the second generation. Thus gout and Bright's disease of the kidneys in the father become rheumatism and sometimes neuralgia in the children. Heart disease grows milder in its descent. Nervous prostration is transformed into sick headache. Blood diseases become scrofula; and so in every way Nature seems to do one of two things, either to slowly cure the disease or else to kill off the race which is afflicted The practical applications of this law are many and of high value. When a person is attacked with a disease that is inheritable, he will not transmit it to his children if he treats it in time and restores his system to a normal condition. If he be thoughtless, lazy or ignorant, and allows the malady to develop until it becomes chronic or constitutional, he will in every probability transmit it directly or in some modified form. In the latter case, he is throwing trouble, suffering and misery upon the innocent, and too often is sowing the seeds of death in the unborn. His children are sick after him, and worst of all, they have impaired constitutions, which often requires years to become sound and efficient. It is this condition which for lack of terms we call "lessened vitality," and lessened vitality in all cases bespeaks ill-health on the part of father, of mother or of both. While it is impossible to prevent the transmission of disease in some form, it is easy to reduce it to so small a factor as to be practically insignificant. As nearly all disease arises from impure blood, as it can be transmitted only by impure blood, and as it can reappear in a second generation only when the blood is impure the whole secret lies in the purification of the circulation of both parent and child If done in time by the former, it will increase to a vast extent the strength and healthfulness of the latter. Whether done in time or not, it is advisable to purify the blood of the offspring. This may be done in various ways,

but in only one which at the same time is certain, speedy, economical and thorough. A good method is a long stay at any hot springs, but this is slow and very expensive. The better way is using Ayer's Sarsaparilla until all the humors of the system are dispelled or destroyed, and both the circulation and the tissues are restored to perfect health. This preparation is a simple and agreeable combination of the most efficient alteratives known to physiology and chemistry. Its formula has been approved by the most eminent physicians. In its purification of the blood, it acts upon every vital function, strengthening those which are weak, stimulating those which are sluggish, and upbuilding those which are impaired. When used regularly by parents, healthy children are the invariable result. When used by sick or sickly offspring, disease and weakness disappear and health is soon restored.

Hot Weather Necessities.

Notice the large square package in the front rank. That's where it belongs—ask any woman who has used it. See what it does. It saves work, saves strength, saves health, time, and temper. It saves wear and tear, too—and that's money. Delicate summer clothes don't have to be rubbed and wrenched when they're washed with *Pearline*. Everything is washed easily—and safely. *Pearline* doesn't *do* any more in warm weather than in cold, but you seem to *need* it more then. It's a necessity. But it's a luxury, as well. Try it in the bath, and you'll think so.

Beware of imitations. 193 JAMES PYLE, New York.

When used by both, a happy, healthy and hearty family bear testimony to the truth of the teachings of science.

BUSINESS NOTES.

HORSFORD'S ACID PHOSPHATE.

Ill effects of tobacco relieved by its use. Dr. F. Le Sieur Weir, Philadelphia, Pa., says: "In certain cases of skin diseases, where the stomach is in a condition unfavorable to the diseases, not infrequently have I found it to correct that condition, when nothing else yielded the desired result."

FIVE THOUSAND MILE RAILWAY.—The great Russian railway from Vladivostock, on the Pacific Ocean, through Siberia to St. Petersburg has been ordered, and operations begun. This road will be 4,810 miles long—with spurs, more than 5,000 miles in all. The cost is estimated at one hundred and sixty millions of dollars. It will open many regions rich in minerals and agricultural productions.

TEXTILE INDUSTRIES IN MAINE.—The capital invested in cotton manufactories in Maine is $15,292,078, and capital invested in Maine woollen manufactures $3,876,028—a total of 19,168,106. The cotton mills use 13,586 horse power water and 1,875 horse power steam—a total of 15,461 horse power—and the woollen mills 3,406 horse power water and 404 steam, amounting to 3,810 horse power—the total horse power for cotton and woollen being 19,271. The cotton mills employ 859.890 spindles and 22,698 looms, and the woollen mills 358 sets of cards and 1,577 looms. The product of the cotton mills aggregates 204,282,000 yards per year—equivalent to 116,069 miles of cloth. The value of the annual product is, for cotton, $13,319,363, and woollen $6,686,073—a total of $20,005,436. The cotton mills pay in wages $2,936,640, and the woollen $1,044,606—a total of $3.981,246. The cotton mills employ 11,759 hands, and the woollen mills 3,095—a total of 14,854 hands.

COTTON SEED SUGAR.—A sugar fifteen times sweeter than cane sugar, and twenty times sweeter than beet sugar, is reported by a German chemist from cotton-seed meal. It cannot be sold to compete with the ordinary article.

ALTERNATE CURRENTS.—Prof. Elihu Thompson finds in his experiments on the physiological effects of alternate currents that the danger of the current diminishes as the number of alternations per second is increased. Thus it took twenty times as strong a current to kill a dog when the alternations were 4,500 per second than when they were 120 per second. When the alternations were 300 per second the current was only half as dangerous to life as when the alternations were 120.

HE HEDGED.—Algernon: I've a widdle for you, Miss Miwanda. Why are childwen like tooth bwushes?

Miranda; I don't know. Why are they?

Algernon: Because evewybody pwefers his own. See?

Miranda (frigidly): No; I don't see. Not having any children ——

Algernon (stammeringly): Oh, of course not; but you-you-you have a tooth bwush, you know.—*Kate Field's Washington.*

BRIEF AND TO THE POINT.—A teacher in a suburban school, not long ago, gave her pupils twelve minutes in which to write an "abstract." A shoe was the subject selected by her, and the boys were to write in the first person. No limit as to the lines or words was given them. Most of the boys wrote—and erased. during the whole time allotted, but the teacher noticed one fellow who sat idle until the time was within two minutes of expiring. As the scholars filed out, she said to him: "Brown, did you finish your abstract?" "Yes, ma'am," he answered. Curious to see what he could have written in so short a time, she looked over the papers and found this: "I am a worn-out shoe; my coffin is the ash-barrel; my grave, the dump." She says that almost as firmly impressed on her memory as this remarkable composition is the expression of amazement on the boy's face the next morning, when he saw the "100" mark on his paper.

WATCHES.

EVERY one wants a watch, and naturally a good watch that keeps accurate time, presents a handsome appearance, and is inexpensive. If such a watch can be found of American manufacture, it is an additional appeal to our patriotism. Just such a watch as this ideal THE ANALYST PUBLISHING COMPANY is enabled to offer as a Premium to its readers. Having some large advertising contracts we have been enabled to procure the movements of the manufacture of the best known American watch factories, namely, the Waltham, Elgin, Hampden and Illinois Watch Companies. These movements are adapted for both ladies' and gentlemen's watches, and are warranted by the makers. These movements have seven jewels, patent lever movement, chronometer balance, patent safety pinion, sunk hard-enameled dial, straight line visible palette, stem winders, hand set; in fact, contain all the latest improvements and can be readily cleaned or repaired by any ordinary good watchmaker. They can be regulated to run as close as any movement.

It is needless to say that to case these movements in solid gold cases would make them too expensive, yet they are cased in what are known as gold filled or stiffened "Ladd" cases, and are warranted to be 14 karat gold, made from two sheets of 14 karat gold overlaying fine composition metal, with regular jointed caps, covers and bezels, and to wear at least five years. They are not plated, nor rolled gold, but actual 14 karat gold cases, thin of course, but stiffened and strengthened by being filled with this fine composition metal. They are finished in the same manner, engine turned and engraved as solid gold watches, and wear and look just the same. No one but an expert can tell them from a solid gold watch. These watches are made both open face and hunting case style, in gentlemen's or ladies' sizes. For gentlemen we recommend plain engine-turned cases; for ladies, a handsomely engraved case.

How to Obtain One of these Watches.

These watches are not to be purchased from us at any price. Send us a club of 25 subscribers to the AMERICAN ANALYST, and $25, the regular subscription price, and one of these watches (your choice of style and size) will be immediately forwarded, post-paid and registered, to your address. You need not wait until you have your 25 subscribers all together, but forward them as you get them and they will be credited to you, and when the number is complete the watch will be sent. A subscription for two or three years will be counted as two or three subscribers.

As these watches are retailed by jewelers at not less than $25, it will be seen that we are offering a real premium with the sole object of increasing our circulation, and that by taking advantage of our offer any one can obtain a good, reliable and handsome watch without cost. As the number of these watches at this price is limited, it is advisable to take steps at once to procure a bargain.

THE ANALYST PUBLISHING CO., 19 PARK PLACE, NEW YORK.

A VALUABLE BOOK FOR NOTHING.

The AMERICAN ANALYST will send to any person who will forward a New Subscription with One Dollar, a copy of

THE FAMILY CYCLOPÆDIA OF USEFUL KNOWLEDGE.

This is unquestionably one of the most interesting, entertaining and instructive books ever published. It is a universal educator for every member of the family circle, filled with useful information from beginning to end, and this information is given in such an attractive and pleasing way that the book is quite as entertaining as it is instructive. It treats of hundreds of subjects of which no man, woman or child who seeks to be well informed can afford to be ignorant, yet of which the masses of people are entirely unlearned. It contains the cream or substance of a dozen ordinary volumes, and is one of the most valuable and useful books a family can have in the house. No living man is so well informed that he may not learn from it. It is a book for the masses, for old and young, rich and poor, and will be read with pleasure and profit by all. It will likewise be found of great value as a work of reference. The book is profusely and elegantly illustrated, and is conveniently divided into departments, as follows: ***Biography, History, Natural History, Travels, Manners and Customs, etc.; The World Illustrated, Useful Arts and Manufactures, Trees, Plants, Fruits, etc.; Great Inventions, Mining, Wonders of the Sea, Familiar Science, Law for the Masses, Statistical and Miscellaneous.*** All the above subjects are fully and ably treated in this valuable book. It is a vast storehouse of useful and entertaining knowledge—unquestionably one of the best and most valuable books ever published in any land or language. No cyclopædia ever heretofore published at twice the cost is to be compared with this book in point of artistic make-up, beauty, and excellence of illustration, and quality of contents. As a holiday or birthday present for any one, nothing more appropriate or acceptable could possibly be selected. THE FAMILY CYCLOPÆDIA OF USEFUL KNOWLEDGE is a large and handsome book of 544 pages, 12mo, printed upon fine paper and elegantly bound in cloth, embellished with artistic designs in black and gold. It contains ***Two Hundred and Seventy-three Beautiful Illustrations,*** the original cost of which was over $5,000. The book will be sent by mail, post-paid, to any person sending a ***New Subscription with One Dollar.*** It is as large and handsomely gotten up as books usually sold at $1.50 and $2.00, and in the quality of its contents is worth a dozen ordinary volumes.

BOSTON HAY AND STRAW MARKET.

Hay, choice to fancy, in large bales	$15.00 to $15.50
Hay, choice to fancy, perpetual pressed bales	14.00 to 15.00
Hay, fair to good	13.00 to 14.00
Hay, poor to ordinary	11.00 to 12.00
Hay, Clover and Clover mixed	10.00 to 12.00
Hay, swale	8.50 to 9.00
Straw, Rye, good to prime	17.50 to 18.00
Straw, Oat	8.00 to

BOSTON, June 6, 1891.

Receipts for the week are 328 cars of Hay and 28 cars of Straw; corresponding week last year, 203 cars of Hay and 25 cars of Straw. The receipts of hay are quite liberal, but there has been a fair demand, and there is no accumulation of stocks. Some cars of strictly fancy hay in large bales are selling at $16.00, but such are exceptional.

Rye straw is steady with some choice cars selling at $18.50. Very little demand for oat, wheat or machine threshed rye straw.

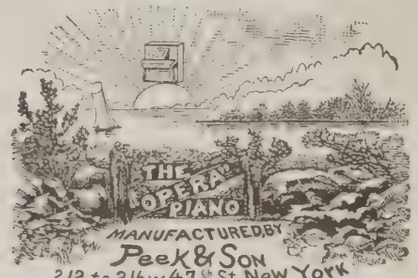
Tabasco Pepper Sauce

OR LIQUID PEPPER.

Is simply the Pulp of the Ripe Pepper Extracted by Pressure.



The seed of this Pepper was obtained from Central America, and by careful cultivation in Louisiana for many years has been so improved in strength, flavor and aroma, as to have become a new variety of Red Pepper, superior to all others. The pulp is so handled as to retain all the flavor, strength, aroma and color of the ripe fruit, and to keep unimpaired in any climate. It excites the appetite, promotes digestion, and is pronounced, by connoisseurs, to be the finest condiment in the world. For medicinal purposes it recommends itself by its purity, strength and diffusible form.

INSTRUCTIONS TO SUBSCRIBERS.

The **Names of all Subscribers** are registered as soon as received, and paper is always promptly forwarded.

Postage.—The postage to all parts of the United States and Canada is paid by the publisher.

Remittances of small sums may be made with comparative safety in ordinary letters. Sums of one dollar or more must be sent by registered letter or P. O. money order, otherwise we cannot be responsible for same. Silver must not be sent in a letter.

Postage Stamps will be received for the fractional part of a dollar, and in any amount when it is impossible for patrons to procure bills, but you must send one or two-cent stamps only.

SUBSCRIPTIONS.—The AMERICAN ANALYST will be sent one year to any subscriber for ONE DOLLAR. New subscriptions can begin at any time.

We Stop the Paper at the expiration of the time paid for unless a renewal of subscription is received. Those whose subscriptions have expired must not expect to continue to receive the paper unless they send the money to pay for it.

Change of Address.—Subscribers wishing their addresses changed must invariably give their former as well as new address.

Missing Numbers.—It occasionally happens that numbers of our paper sent to subscribers are lost or stolen in the mails. In case you do not receive any number when due, write us a postal card and we will cheerfully forward a duplicate of the missing number.

Most Important of All.—In every letter that you write us, never fail to give your full address, plainly written—name, post-office, County and State.

Address all letters to

THE ANALYST PUBLISHING CO.,

GRAND PREMIUM OFFER!

A SET OF THE

WORKS OF CHARLES DICKENS,

In Twelve Large Volumes,

Which we Offer with a Year's Subscription to this Paper for a Trifle More than Our Regular Subscription Price.

CHARLES DICKENS.

Wishing to largely increase the circulation of this paper during the next six months, we have made arrangements with a New York publishing house whereby we are enabled to offer as a premium to our subscribers a **Set of the Works of Charles Dickens, in Twelve Large and Handsome Volumes,** with a year's subscription to this paper, for a trifle more than our regular subscription price. Our great offer to subscribers eclipses any ever heretofore made. Charles Dickens was the greatest novelist who ever lived. No author before or since his time has won the fame that he achieved, and his works are even more popular to-day than during his lifetime. They abound in wit, humor, pathos, masterly delineation of character, vivid descriptions of places and incidents, thrilling and skillfully wrought plots. Each book is intensely interesting. No home should be without a set of these great and remarkable works. Not to have read them is to be far behind the age in which we live. The set of Dickens' works which we offer as a premium to our subscribers is handsomely printed from entirely new plates, with new type. The twelve volumes contain the following world-famous works, each one of which is published *complete, unchanged, and absolutely unabridged:*

DAVID COPPERFIELD,
MARTIN CHUZZLEWIT,
NICHOLAS NICKELBY,
DOMBEY AND SON,
BLEAK HOUSE,
LITTLE DORRIT,
OUR MUTUAL FRIEND,
PICKWICK PAPERS,
BARNABY RUDGE AND CHRISTMAS STORIES,
OLIVER TWIST AND GREAT EXPECTATIONS,
THE OLD CURIOSITY SHOP AND THE UNCOMMERCIAL TRAVELER,
A TALE OF TWO CITIES, HARD TIMES AND THE MYSTERY OF EDWIN DROOD.

The above are without question the most famous novels that were ever written. For a quarter of a century they have been celebrated in every nook and corner of the civilized world. Yet there are thousands of homes in America not yet supplied with a set of Dickens, the usual high cost of the books preventing people in moderate circumstances from enjoying this luxury. But now, owing to the use of modern improved printing, folding and stitching machinery, the extremely low price of white paper, and the great competition in the book trade, we are enabled to offer to our subscribers and readers a set of Dickens' works at a price which all can afford to pay. Every home in the land may now be supplied with a set of the great author's works.

GLENN'S SULPHUR SOAP.

Glenn's Sulphur Soap is the **Original** and **Best** combination of its kind, and the one now generally in use. For sale by **All Druggists.**

BEWARE OF COUNTERFEITS.

Wholesale Depot,

C. N. CRITTENTON,
115 FULTON STREET,
NEW YORK.

Be progressive and keep abreast of the times. Avoid dyspepsia by using **Lard Compound** and **Cottolene,** a substitute for lard.

The highest medical authorities pronounce them healthful; and expert cooks commend them.

Our **Clairette** brand of cotton oil soap is the purest and best laundry soap in the market; as pleasant to the hands as genuine castile.

N. K. FAIRBANK & CO.,
CHICAGO AND ST. LOUIS.

OUR GREAT OFFER

TO SUBSCRIBERS

TO THE

AMERICAN ANALYST.

We will send the **ENTIRE SET OF DICKENS' WORKS,** *in* **TWELVE VOLUMES,** *as here described, all postage prepaid by ourselves, also* **THE AMERICAN ANALYST** *for* **ONE YEAR,** *upon receipt of* **$1.50,** *which is only* **50** *cents more than the regular subscription price of this paper.* Our readers, therefore, practically get a set of Dickens' works in twelve volumes for only **50** cents. This is the grandest premium ever offered. Up to this time a set of Dickens' works has usually been $10.00 or more. Tell all your friends that they can get a set of Dickens' works in twelve volumes, with a year's subscription to **THE AMERICAN ANALYST** for only **$1.50.** Subscribe now and get this great premium. If your subscription has not yet expired, it will make no difference, for it will be extended one year from date of expiration. We will also give a set of Dickens', as above, free and post-paid, to any one sending us a club of three yearly subscribers.

DISCOUNTENANCING BACHELORS.

As a sort of corollary to the description of the Berlin Marriage Bureau, published in our last issue, it is interesting to note that a bill to abolish bachelorhood among state officials will be laid before the German Reichstag shortly. The explanatory and argumentative "motive" such as accompanies all bills before the Parliament of Berlin, will be, in this case, substantially as follows: "In the interest of unmarried women, the Government is under obligations to take measures for the suppression of bachelorhood, especially in view of the fact that German women are not admitted to places in the departments which were formerly open to them. The principle of the necessary marriage law must be that every official of certain grades must marry or sacrifice one-fourth of his salary and all his house money. The money collected by the infliction of these penalties should be made a pension fund for unmarried daughters of Government officials. An exception to the rule might be made in the case of officials who had parents or sisters to support. Thus, many women who would otherwise remain spinsters would be cared for and their aims in life would be reached, while to many who found no chance to marry, a comfortable old age would be assured." The agitation in favor of this measure is helped along by several societies of women in Berlin, Munich, and Frankfort.

THE DOUBT STRENGTHENED.

Our esteemed contemporary, the *New England Grocer*, in its issue of June 5, refers with exceeding bitterness to some comments the AMERICAN ANALYST recently made regarding the projected scheme of the retail grocers in this city for advertising themselves and their wares under the lofty pretext of a permanent "Pure Food" exhibition. Our contemporary should not, we think, wax so wroth, for our remarks were penned in the most amicable spirit imaginable. He should bear in mind that it was he himself who first raised the question whether a man "can keep a grocery store and be a Christian." In attempting to answer his query we did not deny the possibility of such a desirable combination of practical qualities and spiritual gifts, notwithstanding the shadow of dubiousness with which he had invested the notion by the mere fact of starting the inquiry. We simply suggested that there might be localities in which the public would perhaps have its doubts on the subject—such localities, for instance, as those in which "Pure Food" exhibition humbugs are organized as money making advertising ventures. But our contemporary seems to have been so "riled" by our remarks as to have been blinded respecting their meaning. Thus he accuses us of having charged the New York grocer with lack of cleanliness—an accusation which we emphatically repudiate. We said that as a class he is not, as is proverbially alleged of cleanliness, in close proximity to godliness. Perhaps in this degenerate generation, when heresy is rampant on every side, our contemporary regards any deviation from the straight path of orthodoxy as unclean, and in that way misinterprets our meaning. It simply affords a fresh illustration of how the best and wisest of us may err when we permit our prejudices to get the better of our judgment. But it is as a lexicographer that our esteemed contemporary makes the worst showing. We asserted, and we at least had reason on our side, that the borrowing for the grocers' advertising scheme of the English name "Healtheries" suggested that English dudism was acquiring "such a hold upon the community that it must find vent through the grocery store." The *N. E. Grocer* objects to this, and says we "forget that the very essence of dudeism is the use of big words instead of simpler forms of speech." If that is not a corroboration of our assertion we fail to understand it. But our contemporary is wrong here too in his definition. The word "dude" does not appear in any of our English lexicons except the *Century Dictionary*, where it stands thus:

Dude.—A slang term, said to have originated in London, England. * * * A fop or exquisite, characterized by affected refinements of dress, speech, manners and gait, and a serious mien. * * *

Dudism.—The dress, manners and social proclivities of the class known as dudes.

Manifestly the "very essence of dudeism" is not "the use of big words," but is a combination of affectation, humbuggery and deceit, such as is fairly illustrated by the use of the word "Healtheries" in the relationship referred to above. We have no desire to engage in controversy, particularly with so esteemed a contemporary as the *N. E. Grocer*, but appreciating his sense of justice, we have taken the occasion to point out some of the misstatements into which he has been unwittingly misled by his eager zeal on behalf of the trade he so ably represents. If space permitted we could point out several more of his blunders, but to our readers the task would be superfluous. One point, however, we cannot in fairness overlook. The *N. E. Grocer* emphasizes with especial severity our suggestion that the commodities in which the retail grocers deal are sometimes sophisticated—a circumstance which the poet Longfellow doubtless had in mind, when he declared in his "Song of Life," that "things are not what they seem." It would take too much space to enter into this branch of the discussion exhaustively. We will content ourselves at present with reproducing the following brief extracts from two of our valued exchanges:

N. E. Grocer: The difficulty is with the out of the State manufacturers. We believe the State authorities should notify the grocers that the goods are impure, and not prosecute unless the grocers continue to sell after having been so notified. We believe that if there are manufacturers in this State who sell adulterated goods, they ought to be made to suffer, and not the retailer of these goods.

N. E. Grocer: Grocers feel that it is unjust to fine them for selling adulterated food stuffs. * * * The grocers add that they take as great precautions as possible to protect themselves and customers, but the people demand cheapness, and cheapness and excellence of quality do not obtain together. There is, it must be admitted, considerable merit in the grocers' plea.

The N. Y. Voice (temperance organ): The discoveries of the sanitary police are only partly divulged, but the facts published are enough to justify an occasional wish to limit our diet to articles that are sold in the "original packages" of nature, like apples, eggs and potatoes. Half the lard and three-fourths of the butter sold in the markets of our chief cities are not what they seem; most of our bottled honey is glucose flavored with aromatic extracts and wax emulsions; ground pepper and ground coffee, mustard and tea are mixed with surrogates too numerous to mention; but all those things are trifles compared with the abominations of the milk traffic.

PRACTICAL PHILANTHROPY.

The scheme of social amelioration is being variously experimented upon by the philanthropists and charity workers of this metropolis. One of the latest projects of this character, and one that promises well, is an organization founded by a number of well-known gentlemen who have just organized a society, whose object shall be, its constitution says: "To bring men and women of education into closer relations with the laboring classes, for their mutual benefit." The University Settlement Society is the name of the organization. It is proposed that college men shall retain the control of the society, although its membership and management will not be limited to collegians. The society is going to establish in the tenement house districts places of residence for college men and others who desire to take a hand in the work, with rooms where the people of the neighborhood may meet for social and educational purposes. These places are to be called settlements. Some of the men who belong to the society are Felix Adler, Charles S. Fairchild, Richard Watson Gilder, Henry Holt, Brayton Ives, Seth Low, Oswald Ottendorfer, Elihu Root, and Carl Schurz. James W. Alexander is the President, A. C. Bernheim, Treasurer, and J B. Gilder, Secretary. For some time the Neighborhood Guild has been working in this city. Its objects are similar to those of the new society. It has a house in a thickly settled district and its workers are college-bred men. About 250 people of the neighborhood regularly visit the house, and 100 more, not members of the Guild, attend lectures The house has also served as a residence for three or four workers who have regularly visited among the neighbors, and performed various friendly offices for them. During the past year a similar work has been carried on in this city by graduates of Vassar, Wellesley, and other women's colleges, with like success. "It has been demonstrated," says a circular issued by the University Settlement Society, "that educated men and women, living and working among the poor, associating with them as equals, but introducing into the tenement house all that trained intelligence and friendly sympathy can give, can make themselves a most efficient means of bettering and elevating the mental, moral, and physical condition of the people."

UNCONSCIOUS SUGGESTION.

It is by no means a new theory that a man and woman who have been married a great many years grow to resemble each other, not only in manner and voice, but actually as to features and expression. A recent number of the *Illustrirte Welt* has an article on this subject, which states that the photographic association of Geneva has quite lately been investigating the truth of this theory by the aid of the camera. The photographs of seventy-eight elderly or very old married couples were taken, and an equal number of family groups. The result proved quite satisfactory to holders of this theory, inasmuch as in twenty-four cases the resemblance between husband and wife was much greater than that between brother and sister, and in thirty cases more it was fully as great. The failure of the other twenty-four old couples to realize the expectations of those interested in the matter is supposably due to "incompatibility of disposition," which time was apparently unable to combat in its effects.

WOMEN AS ARCHITECTS.

We learn with interest that an award of one thousand dollars has been made to Miss Sophia C. Hayden, of Boston, for her design for the Women's Building at the Chicago World's Fair. A second prize of $500 was given Miss Lois L. Howe, also of Boston, and Miss Laura Hayes, of Chicago, received the third prize of $250. The awards were made by Mrs. Potter Palmer, president of the board of lady managers. The designs had previously been discussed and criticised by the chief of construction, Mr. Burnham, and by other members of the board of architects. The event is of interest, says the *Scientific American*, as indicating the hold that women are taking of the profession of architecture. In many respects they would seem pre-eminently suited for it. Their innate tact and taste, and their appreciation of the domestic wants, are elements which should tell in their favor, at least as designers of houses to be lived in. The field of women's work is rapidly broadening, and this competition emphasizes their entrance into the higher professions.

DEATH VALLEY.

THE RESULTS THUS FAR OF THE GOVERNMENT EXPEDITION.

The Government expedition to Death Valley is bringing forth its first fruits. Large consignments of dead creatures illustrating what it has thus far accomplished in the study of the life of that amazing region have reached the Department of Agriculture at Washington. The collections thus far received include 2,368 mammals, beside numerous birds, reptiles, insects and other specimens. It is desired by the scientific authorities in charge to find out just what animal and vegetable life is able to preserve existence under conditions so extraordinarily unfavorable as obtain in this desert of horror, the like of which is not found anywhere else in the world. Of plants there is scarce anything to be discovered beside cacti, which only represent a sort of vegetable half-life, and clumps of chapparal that are gray instead of green. One sort of cactus, that grows to be five or six feet in height, with extended branches, is called the "Dead Man," because each stalk in the night looks like a corpse by the wayside. In rare spots where water has gathered may be seen a singular fleshy bush without leaves and with thick green stems. Such vegetation as there is is rank and spiny, its gray or dull olive hues harmonizing weirdly with the parched and barren aspects of the great alkali crust, extending north and south between two precipitous walls of mountains, the Amargosa and Panomint ranges. Those who have visited it say that it is beyond human powers of description to picture the wholly unnatural scene to be beheld there—the vast stretches of white plain variegated with black lava, the alluring mirages, the strange appearance of the towering hills outlined like the backbones of monstrous beasts against the yellow sky, the total absence of trees, the dearth of animal life, and the intense heat, from which there is no escape. Here and there, too, are pebble beds miles in extent, made up of agate, moss agate, chalcedony, jasper and obsidian. This astonishing desert, however, is by no means so devoid of life as its aspect by day would lead the observer to imagine. As soon as night falls it is all aswarm with creatures of various sorts. Countless lizards come out of their burrows to look for insect prey, snakes wriggle across the alkali crust, horned toads creep about, and scorpions and tarantulas of enormous size sharpen their claws for combat. Rats, mice and squirrels trot about in active pursuit of game, and wildcats and coyotes forsake their lairs on the mountain sides and roam over the plain in pursuit of all sorts of smaller mammals. It is a nocturnal population, simply because the heat is so great as to forbid going out in daytime. The Death Valley expedition has not attempted to encamp upon the desert itself for the sake of acquiring specimens. It has been obliged to content itself with pitching tents about the edge, at the foot of the mountains, making brief expeditions across the torrid plane, setting traps and returning as quickly as possible. By this method the traps could be emptied and set again without much loss of time. Time is of consequence in Death Valley, where a man requires two gallons of water daily to keep him from dying of thirst, and even then is a sufferer. Little traps of a very simple and most admirable pattern are employed for catching the small mammals. Two or three dozen of them can be conveniently carried in the pockets of one's coat, and the game coveted can enter from any side. Each one is hardly more than a wire spring, ingeniously contrived, so that the victim is not obliged to enter a hole, sees no danger, and does not dream of peril until he is caught. Corn meal is employed for bait, and is found most fetching. For the large mammals the gun must be brought into requisition, while the reptiles, usually slow of movement, are readily gathered in. Of the birds there are very few in the neighborhood of Death Valley, though the raven, that funereal fowl, is very plentiful in the woods that skirt its edge, crying with mournful notes for the many travellers whose dried corpses are scattered over the burning level. As quickly as possible after they are caught the animals trapped and shot are skinned by the explorers, all of whom are skilled taxidermists. No great pains are taken with the stuffing. A lump of raw cotton supplies the place of vitals, and the tail is extended by a wire thrust through its length. Arsenic is sprinkled all over the inside for preservative purposes, and the specimen is stretched with four pins on a board to dry. As soon as they have thus been made ready, the preserved creatures are forwarded to the Department of Agriculture at Washington. Supply wagons travel constantly between the expedition and the nearest outposts of civilization, to get provisions and convey mails. A great many individuals of each species found have to be killed and forwarded, because individuals here and there differ, and it is necessary to determine where these individual differences end and new species begin. For example, one kind of rat may have ears of various sizes and different lengths; but it is requisite to find out the line of demarcation which separates this animal from another species. Thus far the animals sent in to the department are merely such as have been found in Death Valley, because the expedition has been availing itself of the cool weather in that region. Now it has retreated to the mountain slopes, and it will not be possible to conduct any further investigations on the torrid plane until late next autumn. Nearly all of the creatures found in the valley are nocturnal in their habits, because they are not able to venture out in the daytime on account of the great heat. Among them are three species of ground squirrels, which live in burrows and feed at night upon roots, leaves and seeds of plants. One of them often climbs the stalks for the purpose of getting at the seeds. At other times it stands on its hind feet, clasps the stems with its fore paws and bites off the seed-pods, distending its cheek pouches enormously with the food. One fellow, shot by Dr. Merriam, chief of the expedition, had thirty-nine unbroken seed-pods in his pouches. Another most interesting animal that inhabits Death Valley is the "kangaroo rat," which makes its way about by jumping. It has long and powerful hind legs and a surprisingly long tail. Its coloring varies from light gray to dark brown, according to whether it frequents the alkali or the lava, nature intending to prevent it from capture by the likeness of its hues to its surroundings. The kangaroo rat lives in burrows, as does likewise a smaller kind that is commonly called the "kangaroo mouse." But neither is in any true sense a mouse or rat; they belong to families quite different. Nevertheless, there are plenty of real rats in Death Valley, as the expedition has found. One kind that lives in the chapparal, with bare tails and exquisite soft fur, is the staple food of the Digger Indians, who dwell in the mountains thereabout. The latter catch the beasts with dogs, frightening them out of their nests, which are made like those of squirrels, of great size, in the bushes or bunches of cactus. With respect to the kangaroo rat, one extraordinary point should be mentioned, relating to a certain development of their skulls, which bulge out at the sides in a surprising way. In fact, no such big bulges as these, which con-

tain the heating apparatus, are to be found in any other known animals. One of the most curious sorts of rodents common in Death Valley is the "scorpion mouse," which lives almost wholly upon scorpions. By the "instinct," which means experience, inherited through generations, it has learned which end to tackle its prey by. Another creature in the same region that likes scorpions also is the "chapparal cock," which gobbles them by thousands, and is not less fond of centipedes, tarantulas, lizards and horned toads. The last named are too big to swallow at a gulp, and so the fowl tears them to pieces before devouring them. Perhaps the most beautiful mouse in existence is found in Death Valley, and is known as the "grasshopper mouse." It is a lovely beast, fawn-colored on the back, with a snowy belly and sides, a short tail and pretty little ears. Other mammals forwarded hither from thence are "pocket mice," with pouches outside their throats to store provisions in, gophers, weasels, shrews, and a newly discovered species of lavender-gray fox with long ears. A wonderfully big species of coyote has been found in the valley. One funny thing about this kind of animal is that it is enormously fond of watermelons; but it has to starve for them out there. Only fifty miles west from Death Valley, which is one hundred and fifty feet below the sea level, Mt. Whitney, the highest mountain in North America, up lifts its mighty peak, covered with perpetual snow, three miles into the air. Thus within a day's journey of each other the lowest and the highest point on this continent are found. Dr. Merriam wrote that he had breakfasted on top of twenty feet of snow and was composing his letter to Secretary Rusk, at 4 P. M., in an altitude of rather less than nothing and a temperature of 110 degrees Fahrenheit in the shade. The expedition would be very glad to ascend Mt. Whitney, but the task is likely to be an impracticable one. Above there are depths of snow which are continually precipitating themselves in avalanches. Below, on the lower slopes, the dissolving ice has reduced the ground to the condition of a hopeless morass, through which travel is altogether impracticable. There is no path up the mountain by which even a mule could journey. In the region described is to be found a most astonishing opportunity for the observation of a traveler, inasmuch as within fifty miles he can pass through all the life-zones of the earth, from the hottest tropic to the frozen Arctic, and view not only the vegetation, but the beasts and birds of the various climes traversed. It seems very strange to find upon the summits of Mt. Whitney, the San Francisco Mountain and other peaks scattered over the warmer parts of the earth, small colonies of veritable Arctic life, both vegetable and animal. But this is explained when it is realized that during a period immediately preceding the present, and known as the "glacial age," the entire northern part of the world was buried in ice, the ice-cap, which in places was several thousand feet in thickness, extending southward as far as Philadelphia. When this vast cosmic glacier receded, many Arctic plants and creatures were stranded on high mountains, where at sufficiently lofty altitudes the temperature never became too high for the continuance of their existence. For an example, the San Francisco Mountain in Arizona is an extinct volcano, inhabited by plants and animals which could not possibly have reached it since the glacial period. Though an isolated peak rising out of a vast and burning desert, its snowy top is a veritable Arctic colony.

RECOVERED AND NON SUITED.—Here is a queer case for an action. A man was insane and determined to throw himself out of the window of the asylum. He made several attempts, and was prevented by the servants. Put in a new apartment he tried it again, jumped out of the window, fell on the lawn, injured himself seriously, but, strange to say, the shock cured his mental disorder. At once he sued the officers of the asylum for negligence. The plaintiff was nonsuited. There is a delightful legal quibble about this, for the pros and cons are many.

MINUTE ORGANISMS.

THE REALM OF THE MICROBE IN NATURE.

All living things throughout the animal and vegetable kingdoms are composed of cells, springing, in the first instance, from one single cell. The entire human child, with all its great future possibilities, is, as Hæckle says, in its first stage only a single ball of *protoplasm monerula*. But at the other end of the scale we have microscopic organisms, existing as simple cells, capable of performing all the functions of life, and of playing an important rôle in the economy of nature. Pasteur, in the course of his study of the germ theory, argued that all that has lived must die, and all that is dead must be disintegrated, dissolved or gasified; the elements which are the substratum of life must enter into new cycles of life. One grand phenomenon, he saw, presides over this work—the phenomenon of fermentation. What, then, is the cause of fermentation? In order to answer this profound question, Pasteur devoted himself to the study of the microscopic beings, which he finally divided into two great classes, the aerobies and the anaerobies—those which require free oxygen for their existence and those which are killed by the presence of free oxygen, although able to wrest oxygen from the materials whence they derive their nourishment. The aerobies are those which begin work on the surface of things, their mission being to clear the earth by a process of slow combustion of all that is dead. The anaerobies, working simultaneously, spring into activity underneath the surface of putrescible matter, and, dying on exposure to the free oxygen of the air, are, in their turn, swept away by the aerobies on the surface. Thus the two classes of minute living organisms co-operate towards the fulfilment of a common end, the one beginning work which the other takes up and completes. But for their united efforts we should cease to live, for the earth would be littered with fallen debris and organic matter of every kind, all of which it is their function to transmute into the very elements which are necessary to life again. In the parts of the earth where these organisms do not exist there is no vegetation, no organic matter, no life of any kind; the region is one vast field of ice, a sandy desert, or an expanse of eternal snow. When perchance these desolate places are invaded by living creatures who starve and fall by the way, there is no decay, for the organisms whose office is that of putrefaction are not present to perform their analytical functions. "Thus," says Pasteur, "the destruction of everything that has lived reduces itself to the simultaneous action of these three great natural phenomena, fermentation, putrefaction and slow combustion. The carbon, the hydrogen, the nitrogen of organic matters are transformed by the oxygen of the air and by the action of these aerobies into carbolic acid, vapor of water and ammonia gas." Having thus recognized the vast importance of these minute organisms, Pasteur, the chemist, watched, with unceasing interest, the work of these greater chemists in Nature's own laboratory. Not only were they engaged in the immense business of preserving the balance between life and death, but they participated largely in the every-day work of the world, and were taking an active part in the industries of man. The power of these lowly and invisible creatures is so enormous that they are well called "the masters of the world." If we neglect the laws of health, they are the Nemesis which deals punishment; for in the steady, ceaseless pursuit of duties they spare none. All organic matter is the same to them, whether it be the human body, living, or the dung-heap at the cottage door. In nature some of these organisms live only in living bodies, and are consequently distinguished as parasites, while others live on dead bodies, and are known technically as saprophytes, but in the laboratory both forms, as a rule, can be cultivated on artificial material, rabies being an exception, as it can only be cultivated in the living bodies of animals. The Rev. Dr. Dallinger, who keeps a museum of living putrefactive organisms, describes one of them, to which he has devoted special attention, and thus reveals the marvelous workings of nature in a world we cannot see. This creature is so minute that the average measurement is $\frac{1}{10000}$ of an inch in length and $\frac{1}{15000}$ of an inch in breadth. Nevertheless, it has six flagella, each one of which is three times as long as the length of its body. The movement of these creatures is exceedingly beautiful and graceful, with the long flagella waving to and fro. After a moment's rest the group under observation will be seen to start into active movements in a series of wave-like leaps, reminding one of the movements of a shoal of porpoises, which is continued for from ten to fifteen undulations. This organism, unlike others described by Dr. Dallinger, was never anchored, and had no power of attaching itself, but by freely darting upon the matter attacked, such matter was visibly, in the course of half an hour, reduced in size and altered in shape. Each one in turn, in a space of about two seconds, comes into contact with the particle and at once recedes to a distance of four or five times the length of the flagella, and instantly again darts upon the object, and this may be continued by given forms for hours. Fifty to a hundred may be seen with ease in one microscopic field pursuing their untiring work. It is the more entrancing that it is apparently rhythmical, not like the measured march of a regiment, but the rhythmic movement of a peal of bells. These are examples of the putrefactive organisms at work throughout nature, in company with a vast number of other forms, all engaged in ridding the world of putrescible matter. It is difficult to imagine any study more fruitful in happy results to mankind or more intensely fascinating to the student than that comprised in the new world of the invisible. The point where perhaps most discussion has taken place is that on the border line between the pathogenic and the non-pathogenic organisms. In some cases, for instance, that of the *Bacillus subtilias* and the *Bacillus anthracis*, the difference is so slight that it can hardly be detected under the microscope, yet the one is harmless to man and the other deadly. From the study of the familiar fermentation of yeast Pasteur passed to the study of the diseases of beer and wine, and thence to the silkworm disease, which latter proved the connecting link which established the general relationship between the diseases of beer, wine, and all putrescible things, with the diseases of all living creatures from silkworms to man.—*Mrs. Priestly, in Nineteenth Century.*

SCIENCE AND THINGS.—Lord Salisbury, in a recent lecture before the Chemical Society of London, said: "Astronomy is, in a great measure, the science of things as they probably are, geology is the science of things as they probably were, chemistry is the science of things as they are at present." To these adds the *Electrical Engineer*, "electricity is the science of things as they probably will be."

WARMTH AND VENTILATION.—Suppose a medium-sized sitting room with four people and two gas jets; the air must be changed every fifty minutes to keep it pure. As air is heated it expands and becomes lighter per cubic foot. If all the air is heated equally, it remains at rest after expansion; but if hot air is in the presence of cold air, the latter, by reason of its greater heaviness, forces its way down and drives the hot air up. The moving force of air currents is the greater weight of the colder air. This, then, is the force by which we are to drive out foul air and put pure air in its place. Pure external air will always drive out foul air if you give it a chance. In a room the air arranges itself according to its temperature; the hottest lies along the ceiling, the coolest along the floor. The hottest is the newest and purest. The coolest is the oldest and therefore the foulest. The air is gradually cooling from contact with the walls and windows. When hot air enters a room it rises at once to the ceiling and spreads across it. If there is an escape there, an open window or ventilator, it goes out, leaving the cooler foul air almost undisturbed. From this we see that a window slightly open at the top may cool a room but not purify it.

LAND NAVIGATION.

A CALIFORNIAN'S CONTRIVANCE TO CLIMB MOUNTAINS, CROSS STREAMS, AND EXPLORE WILDERNESSES.

Plans worthy of the authorship of Jules Verne have been undergoing a process of slow evolution in the brain of C. M. Lemery of East Oakland for nearly four years, and now if he had $150,000 he would confidently begin a most remarkable expedition with a remarkably novel contrivance. He has completed working drawings of a queerly contrived "land ship," with which he proposes to roam through the undiscovered gold regions and the unexplored plains and depths of Africa, discovering long-lost deposits of riches, the source of Solomon's gilded glories, gathering tons of precious ivory, revealing the unknown in books of travel and adventure, and generally winning wealth and fame if success shall reward his hopes. His "land ship" is a big car of aluminum, strong and light, which is to climb mountains, jolt over logs, travel through forests and over plains, and, like a duck, plunge from the banks of rivers and lakes right into the water and speed uninterrupted to opposite shores. This contrivance would be at once the home, fort, shelter, means of transportation, and travelling storehouse of the exploring party. It is not the first attempt to combine a steam road engine and steamboat, yet the application appears to be an original one with Mr. Lemery. Mr. Lemery seems to be neither an enthusiast nor an adventurer. He has no particular ambition to be a great explorer, and the whole thing to him is a business proposition. He is a quiet-mannered man, 31 years old, and is a machinist and engineer by trade. He has been on the Pacific coast fifteen years, and during four years of that time was in business at Reno, Nev. He has spent a good deal of time prospecting for gold, and as a prospector he spent a good deal of time exploring the Sierra Madre Mountains in Mexico. About four years ago he became impressed with the idea that the Dark Continent was the one remaining new country where a poor man could get rich easily and the idea has clung to him ever since. He believed that there was plenty of gold in African mountains forgotten or yet undiscovered, and he believes so yet. He wanted to go there to prospect for mines, and in planning how he could travel long distances through an almost unknown country the idea of a steam-engine to travel on land early occurred to him. His mind was busy with his African prospecting engine for months, and a year and a half ago he made a small model of one. He broke it up and went on developing his plans. Three months ago, with the aid of a civil engineer, he completed drawings of a contrivance satisfactory to himself. As strength and lightness are requisites, Mr. Lemery proposed to build the "land ship" almost entirely of aluminum, which weighs 168 pounds to the cubic foot, while steel weighs about 475 pounds to the cubic foot. The cylinders of the engines would be of steel and much of the fittings and furniture inside of wood, The body of the land ship as planned is 50 feet long, 13 feet wide, and 7 feet high. It is to be made of aluminum plates one-fourth of an inch thick for the lower half and one-sixteenth of an inch thick for the upper half of the sides and roof. In the rear end is a large space for wood, which can be cut and loaded anywhere, and the boiler stands abaft the centre. At the forward end are two twenty-four horse-power cylinders working a shaft which bears a wheel outside the car at each end. By an endless chain the motion of this wheel is transmitted to a larger one between the two main wheels, fourteen feet in diameter, which are driven by means of chains passing over the driving-wheel between them. The main wheels are built like a bicycle wheel, the spokes being aluminum rods one-fourth of an inch in diameter. The tires of the main wheels are eighteen inches in diameter. The large wheels have no axles connecting with the car. The car rests on a shaft which passes through the driving wheels and the main wheels are connected by a strong aluminum bar which supports the car and can revolve on the main shaft. The wheels could thus go over logs without elevating the car much, and the end of the bars bearing the front main wheels can be hooked up readily, making a three-wheled car, easy to turn around. The front of the car rests on a single wheel, which turns readily in any direction. At the front end is a drum, on which 800 feet of cable, to pull the car if necessary, or pull obstructions out of the way, can be wound by a small engine for the purpose. The bottom of the car is a water-tank, while another water compartment surrounds the outside of the car. The interior is to provide living accommodations for twenty men. As a steamer the body of the car or "land ship" resembles on its bottom a flatboat or scow schooner. A lever connects a propeller shaft with the machinery, and as the land ship climbs down into the water and begins to float, the propeller sends it onward over the glassy surface of some crystal lake, rippled only by the awful hippopotami. If the water trip be long the land wheels can be taken off and laid on the roof. When wood is to be cut the propeller is slipped off its shaft, and a little wood saw chews up fuel in no time. The engineer works the land ship from his pilot house in front. The whole car is planned to weigh fifteen or twenty tons. "You see," said Mr. Lemery, as he explained his drawings yesterday, "every part will be made so that it can be taken off very readily. I would expect to make from three to twenty miles a day with it, according to the troubles met in clearing away. They would be great in a forest, but I would avoid forests. Attached to this land ship I would have another car just like this, except that it would have no machinery, and in it I would take a three years' supply of provisions and ammunition. The expense of an army of porters would be avoided. The car would be proof against the arrows of hostile natives, and in it we could defy thousands. I would not expect any trouble of that kind, however, for there is always a way to get along with savage tribes. The sight of our land ship steaming through their country would likely scare them out of it. Well, I haven't been able to figure closely on the cost of the ship yet, but I suppose one would cost about $20,000. I would like to get financial backing enough to build two of them and two supply cars in New York, and I ought to have $150,000. I would calculate on being gone five or six years. I would go mainly to prospect for gold. That country is full of it. No, I don't know just where I would go to look for it. I would go to most any of the mountains—perhaps the Mountains of the Moon. No, I do not know whether they have been prospected or not, but I don't think so. Oh yes, there's plenty of gold there. Where else did Solomon get his gold? I would take a company of strong men with me. I would have three or four mining experts, a doctor, a man to write the book, a photographer and a scientific man or two. There is ivory to be traded for in the interior, and ivory is worth $6 a pound. I could carry tons of it. The book and views would be worth a good deal of money. I don't know just where I will look for the money now. Two years ago Senator Hearst heard of my scheme and told me he would back me when it was ready."—*San Francisco Chronicle.*

CITY FLOWERS.

HOW THE METROPOLIS IS SUPPLIED WITH BOUQUETS.

Big and beautiful red roses bloomed near a Broadway florist one evening, and he talked to a *Sun* reporter freely of the prosperity that had crowned the steadily growing business of supplying Gothamites with flowers. White blossoms and abundant greenery made a background and a striking contrast for the great mass of odorous red. A delicious perfume filled the room. Electric lights in ground-glass globes threw a soft yellow glow over the display.

"June, the month of roses," said this wise florist, "is the salvation of the hot weather trade in flowers in the metropolis. It is, so to speak, a sort of financial buffer to break the effect of the dull season that comes with the summer months and their plentitude of lovely flowers. Jacks are all the rage now, and they are beauties, and more abundant than the lilies of the field even. They make a handsome boutonnière for the promenade. They can be bought at retail now at prices ranging all the way from 50 cents a dozen for the pot growth jack to $1.50 a dozen for the best and richest cut variety. Thousands of them are brought into the city every day. One grower alone sends as many as 4,000 to 5,000 a day. Most of these come from New Jersey and Long Island, and the interior of the State supplies the rest. They are received in great heaps at the Thirty-fourth Street Ferry, at the Grand Central Station, and at the Weehawken, Cortlandt Street and Desbrosses Street ferries. Their great abundance makes June the harvest time for the tenement dwellers on the east and west sides of town, who love flowers as much as the wealthy do, but whose limited means deprive them of the opportunity of gratifying an elevating and beautiful fancy at any other time of the year. There is a boom that is also a boon to the people. When the jacks go out all that remains practically to yield a profit to the retail dealers is the steamship and out-of-town trade. All summer long florists supply flowers to tourists who are going to Europe. That branch of the trade is improving, I believe. It consists chiefly in making up baskets to be displayed on the tables of the dining rooms of the outgoing steamships. There is some business, but not so much, in supplying bouquets for the pretty girls who are bound to Europe. A good bouquet can be purchased for $2 or $3. Baskets of flowers cost from $5 to $25. The latter sum will secure something really artistic in appearance. The only other thing that the dealer does in the summer time that is profitable is to supply out-of-town orders from the East and West for cut flowers. New York is the great centre of supply for surrounding cities and towns. Of course, there is a demand all summer long for boutonnières, but very little money is made at it, for the flowers are so cheap, and the quantity bought at any one time by an individual customer is necessarily limited. The stock is very perishable, moreover, and that has a sort of discouraging influence, and the business of the dealer isn't circumspect." The florist led his visitor to the summer storehouse for cut flowers. It was a huge double box about seven feet in height, with an interior very much like that of the giant refrigerators used by butchers and liquor dealers. In the top was a long trough filled with ice. He touched a key and the interior became brilliant with electric light instantly. Cut flowers were heaped on the floor of the refrigerator. Roses were laid in great profusion on shelves, or were blooming in vases. The mass of color was a delight to the eye. In the corner of the refrigerator were thermometers to enable the florist to keep the temperature always at an even degree and to guard against making the atmosphere too chilly. "Flowers will keep in perfect condition for three days here," he said, "but no longer. They begin to fade on the fourth day, and are good for nothing on the fifth. Here we store, in addition to the roses, peonies, sweet pea blossoms and corn flowers, which are also abundant and in demand for ornamental purposes at this season. There is a regular fashion in boutonnières nowadays. Colored flowers are the proper thing; for example, for the promenade, but at night the buttonhole flower must be white. It makes an agreeable contrast against the black of the dress-coat. White pinks are favorites for evening wear. Gardenias make a very pretty nosegay, too." "Which is the most profitable season?" "The Easter holidays are far and away ahead of any other season, not even excepting New Year's, which used to be the great day in the retail trade. The custom of sending ornamental cards as an Easter offering is gradually being superseded by gifts

of handsome flowers. Some of these floral gifts are very rich and beautiful. They are made up in ornamental baskets, and cost anywhere from $5 to $100, according to size and design. Twenty dollars is about the average cost of an order for an Easter basket. Christmas is a very busy day for the retailers. Church decoration is not, however, so much a feature of the day as it used to be. Retailers get very many more orders for flowers for private parlors for Christmas than for churches. The same rule applies to the trade on New Year's Day. The custom of displaying flowers in the parlor then is growing each year, and I don't think anybody will dispute that it is a pretty custom and worthy of encouragement. One of the features of the flower trade in this city is the great popularity of violets. This lasts from November until April. Millions and millions of bunches of violets are sold during that period. Men are fond of wearing them in their buttonholes, and as for women, well, they have a veritable passion for the fragrant and handsome blossoms. But you mustn't make the mistake of thinking that all the profit of the florist's trade is made in cut flowers exclusively. The successful florist is the one who cultivates a specialty. He can make a reputation, if he is a capable man, for one or two particular things, and keep his stock so superior that no other florist can successfully compete with him. He may make a fortune in time in dealing in foliage plants or flowering plants, and pay little or no attention to the cut flower trade. Or, if he chooses, he may turn his attention to roses, or violets, or chrysanthemums, or orchids or any other particular thing that enjoys popularity. There is more to the flower trade," he added, "than most people know, and its details are complicated. An army of men and women are kept busy making wire and baskets expressly for the cut flower trade. To make money at all the retailer must have capital enough to be independent of any particular grower. The competition of the trade is so great, that, to keep customers, the retailer must secure the best. Something may happen to the flowers grown by one particular grower, and the retailer is badly handicapped if he is compelled to take inferior stock. The middleman may become an important aid in solving the difficulty for the perplexed retailer. There are half a dozen middlemen in the trade who deal with all the great growers, and they keep the retailers posted as to the extent and character of the stock of the different growers and protect him from risk. The census bulletin of April 20 should be read by all those interested in the growth of the popular taste for flowers. The bulletin tells the story of a hundred years' progress in detail. It shows, for example, that while there was only one commercial florist in the land in 1800, florists' establishments are now numbered by the thousands, and are in every State and Territory, excepting Idaho, Nevada, Indian Territory, and Oklahoma. Women conduct 4,659 of the establishments. The trade gave employment in the country last year to 16,847 men and 1,958 women, whose combined wages aggregated $8,483,657. More than $1.500,000 was expended for fuel for the hot houses, and 3,425,600 wholesale and 17,630,094 retail catalogues were issued. Tools and implements valued at $1,587,693 were used last year, and the total estimated value of the entire plant of the trade in the country was $38,355,722. The total product of roses was 49,086,253 ; of hardy plants and shrubs 38,380,872, and of other plants 152,835,292, valued at $12,036,477. More than $14,000,000 worth of cut flowers were sold in the past year. The State of New York, according to the census, leads the Union in the extent of its business. It has 793 florists' establishments, 50 of which are carried on by women. They are valued at more than $9,000,000. Pennsylvania is second, with 544 establishments, Massachusetts third, with 407, and New Jersey fourth, with 366. New York florists give employment to 3,172 men and 240 women. More than $2,000,000 was paid as wages to the men and $66,000 to the women. The census bulletin gives an estimate of the relative popularity and profit of commercial flowers. Roses, of course, lead, with carnations next. They represent 65 per cent. of all the sales. Violets, chrysanthemums, lilies, hyacinths, smilax, bourvardia, heliotrope, pansies and tulips, in the order named, represent 25 per cent. more, while the remaining 10 per cent. is made up of orchids, tube roses, mignonettes, primroses, camellas, daffodils, etc. As to the profit made on the sales of the several varieties of flowers, the census reports roses as the best paying, carnations second, violets third. There is a demand for aquatic plants, and the development of these is now becoming a specialty of many growers."

DOMESTIC DIETETICS.

SPECIALLY PREPARED, FROM PRACTICAL TESTS, FOR THE LADY READERS OF THE "AMERICAN ANALYST."

SEASONABLE FOOD.

June.

MEAT.—Beef, lamb, mutton, ham, kidneys, liver, sausage, veal.

GAME AND POULTRY.—Pigeon, chicken, duck.

FISH.—Anchovy, bass, bluefish, blackfish, cod, eels, clams, flounder, haddock, halibut, herring, lobsters, mackerel, mussels, perch, porgie, prawn, salmon, shad, turtle, trout, sturgeon, whiting, weak-fish.

VEGETABLES. — Beans, cucumbers, carrots, cauliflower, lettuce, onions, parsley, parsnips, potatoes, shallots, spinach, turnips, radish, rhubarb.

FRUITS.— Cherries, strawberries., bananas, pineapples.

PRACTICAL RECIPES.

SOUP STOCK.—Take a shin bone weighing five pounds, and pour over it a gallon of cold water and let it stand on the back of the range, where it will heat up very slowly for nearly an hour, then let it cook briskly for half an hour, add a little cold water, skim and set it back again to simmer for five hours, then add a little parsley, one or two bay leaves, seven cloves, a stalk or two of celery, an onion quartered, a carrot and a turnip cut in good sized pieces. Let it simmer another hour, then strain and season, and keep in a cool place for soups and gravies.

SHAD WITH SPANISH SAUCE.—Select a small shad and split it and remove the backbone, wash and dry it. Pound to a paste a little garlic with two red peppers that have soaked for a minute in hot water; pour a little of the water in which they soaked into the paste as you pound it. Put a cupful of olive oil into a saucepan, add to it a teaspoonful of sharp vinegar and a little salt, when it is hot add the pepper-paste, cook for a moment, then pour it into a frying-pan and fry the shad in it; season with salt and pepper and dish; pour the sauce around the fish and serve.

TRIPE AND OYSTERS.—Wash a pound of tripe thoroughly in cold water, then cover it with fresh water and add a gill of vinegar and a little salt. Let it stand an hour; drain quite dry, cut it into neat square or diamond shaped pieces and boil three-quarters of an hour in water slightly salted. When it is done take out the tripe and add to a quart of it a large tablespoonful of butter, half a saltspoon of white pepper, a dash of lemon juice and a tablespoonful of flour dissolved in half a cup of milk. Whisk the milk and flour until free from lumps, and allow it to remain on the range until it becomes thick and smooth, then add the tripe and half the quantity of raw oysters and a little grated nutmeg. Let it remain on the range ten minutes longer, then serve.

BAKED CREAMED LOBSTER.—Cut a good sized lobster in half, take out the meat and save the shells. Cut the meat in small slices. Put two tablespoonfuls of butter in a saucepan, and add to it a teaspoonful of finely chopped young onion, cook them together for a moment, then add a tablespoonful of flour, mix this thoroughly with the butter and add a cupful of milk; boil for a few moments, then put in the lobster and seasonings of salt, cayenne and chopped parsley, let it boil up well, then add the beaten yolk of an egg, take from the fire and fill the shells with the mixture, brown in the oven for a moment then serve.

IMPERIAL DINNERS.

HOW THE EMPEROR OF GERMANY ENTERTAINS.

A dinner in the new palace at Potsdam, near Berlin, is a much grander affair than it was under the more recent predecessors of Emperor William II. The person honored with an invitation receives a great vellum card, carrying the united coats of arms of the Emperor and the Empress. The wording of the invitation is: "At the supreme command of their Imperial and Royal Majesties, the Head Court and House Marshal has the honor to invite —— to dinner, on ——, at 7 o'clock, in the new palace at Potsdam." On the reverse side are several directions as to the dress of the guests. Military men are ordered to appear in undress uniform, and civilians in knee breeches and shoes, dress coats, and white cravats. Guests who are to arrive by train are informed that carriages will meet them at the Wildpark station. A small time-table of trains returning to Berlin after the dinner is also given. The gorgeousness of a great dinner in the new palace has been described pretty fully by German snobs who worship this splendor, and German radicals who find in it a reproach to "the workingmen's Emperor." The details of dinners at which only the nearer acquaintances of the imperial and royal pair are present are, however, comparatively unknown. The number of guests at a great dinner is usually about sixty to sixty-five. The dinner consists of some ten courses, and is served in a few minutes less than an hour. There is one servant for every two persons at the table. The dishes are prepared in the imperial and royal kitchens at some distance from the palace, and are transported thence on a little underground railway, with its terminus near the dining room. The principal dishes are served on silver platters, the others on china of the royal Berlin manufacture. The crystal wine-glasses have broad gold bands and bear the combined monograms of the Emperor and Empress. The quality of the wines at the imperial table is the best to be had in 'heimers and 'bergers, and inferior to few in imported brands. German champagne is drunk only with the soup; otherwise French champagne is served. The table is decorated with huge masses of flowers, mostly roses, which are the Empress's favorite flower. Before every cover there is a small bunch of roses in glass. The room is lighted exclusively by wax candles in silver candelabra. At every place there lie a menu and a musical programme. Both are on white vellum, are ornamented with the united coats of arms of the Emperor and Empress, and bear only German type. Not a single foreign word appears on the bill of fare. At the top are the words "Imperial Dinner." The musical programme contains between twenty-five and thirty numbers, mostly by the Emperor's favorite composers, Wagner, Delibes, Meyerbeer, Weber, Sullivan, as well as a few military pieces. After dinner the entertainers entertain with conversation, but only a chosen few participate in it. The Court Marshal and Chamberlains usually learn in advance whose society is desired by the imperial couple during the evening, and these persons are escorted to the spot where the Emperor and Empress await them. In Potsdam such a dinner as the one described is usually given in the Jasper Gallery, and coffee is served in the shell salon. The music is played in the garden.

DICTIONARY LORE.

SOME COMMON MISTAKES IN PRONUNCIATION.

How many people are there who pronounce any proportion of their words correctly, not merely by reason of clipping and mouthing, but by ignorance of good usage? We find them everywhere, and they lay the accent on the first instead of the second syllable of acclimate, for example; they pronounce the second syllable of acoustics coo instead of cow; they do not put the accent on the last syllable of adept, as they should do; they leave the u sound out of buoy; they pronounce duke with the sound of oo instead of with the simple long u; emphasize the first instead of the second syllable of enervate, and sound the t in often. They are astonished to know that precedence has the accent on the second syllable and placard on the last; that quay is called key; that sough is suf; that the z instead of the s sound is to be given in sacrifice, and the reverse in rise; that subtile and subtle are two different words; that the last syllable of tortoise is pronounced "tis" instead of "tus;" that it should be used and not ust; and that it is not the "zoo," but the zoological gardens where one goes to see the chim*panz*ee, and not the chimpan*zee*. It is quite time, we think, when we hear one of these talkers, for some of the fancy work and fancy studies of the day to be dropped, and a little hard work on the dictionary put in their place.

AMERICAN NAMES.

A GOVERNMENT BOARD FIXES THE SPELLING OF NAMES OF TOWNS AND CITIES.

The second Bulletin of the United States Board on Geographic Names has been received by the AMERICAN ANALYST, containing a long list of names of countries, cities and towns, rendered according to a system of spelling that is in future to be the law. Many changes from old established usage are presented in the compilation before us. Thus the *Evening Post* of this city, which, whatever its other shortcomings, is an acknowledged authority in literary purism, includes in its *index expurgatorius*, the solemn caution to its editors, contributors, proof-readers and printers, that only four places in the United States, viz., Pittsburgh, Williamsburgh, Plattsburgh and Newburgh, spell their final syllable with an *h*—a statement wholly at variance with the orthograhy of the Post-office and other recognized official authorities. But in future, irrespective of any editor's dictum, the terminal "burg" is to be of universal application in such cases, as that is the verdict of the American Board of Geographic Names. Similarly with the "boroughs." There are to be no such things henceforth. Every one of them is declared officially to be a "boro" from this time, and the decision to this effect has gone forth beyond the possibility of recall. The object of the Board in making the alterations is to simplify spelling. This geographic spelling reform movement was begun chiefly because of uncertainties which exist respecting the names of places and features of landscape all over the United States. The Land Office surveyors, in laying out the country, have applied their own nomenclature to the regions which these surveys covered; but the names they selected were very apt to be altogether at variance with those adopted by the residents subsequent or otherwise, and this has given rise to confusion. On top of this comes the Post-office system, which has its own titles for localities numbering hundreds of thousands. Thus it frequently happens that disagreements occur, and "Cameron Post-office" is found to be located in the village of "Hamilton," for no earthly reason whatsoever, and other contradictions likewise. This makes constant trouble. Furthermore, the Coast Survey and the Light-house Board have hitherto had no agreement as to names, and here was more opportunity for misunderstanding. It is readily comprehended how the value of maps must be impaired by a mixing up of names. Obviously it is important that every locality and geographic feature should have its own appellation, and only one: therefore it has been decreed that such shall be the case, and the Board has entered upon the accomplishment of this purpose with "uniformity and simplicity" as its shibboleth. What it determines is the law. It is perpetual, unless some future President smashes it. A suggestion was made to the effect that its members should have power to appoint their own successors, but to this Mr. Harrison refused to agree, conceiving that the geographic spelling censorship ought not to be vested in the hands of a close corporation. The Board is composed of Prof. Mendenhall, Superintendent of the Coast Survey; Capt. Henry L. Howison of the Light-house Board; Capt. Thomas Turtle, Corps of Engineers; Lieut. Clover of the Hydrographic Office; Prof. Otis T. Mason of the Smithsonian Institution; Herbert G. Ogden of the Coast Survey; Henry Gannett of the Geological Survey; Marcus Baker of the Geological Survey, and Pierson H. Bristow of the Post-office Department. One of the first orders communicated to the Board after its recent appointment by the President was given by the Census Office. It called for a full list of the correct names of all the incorporated towns in the United States, numbering about 30,000. It may be imagined that the task has been no easy one, but the rule followed uniformly has been to accept the spelling locally approved, unless some insurmountable objection arose. Post-office lists have had to be compared with other authorities, and there has been no end of trouble in reconciling contradictions. A directory of Alaska was demanded early in the Board's existence, and it has been compiling the work ever since, reducing the geography of the great Northwest Territory to orthographic correctness. Following the same lines it proposes to cover the whole world, time only being needed for the purpose. The Board thinks it most desirable to keep all names, so far as may be possible, just as local usage indicates them. Even where designations

Buffalo Lithia Water, Spring No. 2, in Bright's Disease, Gout, Stone in the Bladder, and Diseases Generally of Uric Acid Diathesis, Etc., Etc.

DR. WM. A. HAMMOND, of Washington, D. C., Surgeon General U. S. Army (retired), Professor of Diseases of the Mind and Nervous System in the University of New York, etc.

"I have for some time made use of the BUFFALO LITHIA WATER in cases of AFFECTIONS of the NERVOUS SYSTEM, complicated with BRIGHT'S DISEASE OF THE KIDNEYS or with a GOUTY DIATHESIS. *The results have been eminently satisfactory.* Lithia has for many years *been a favorite with me in like cases, but the* BUFFALO WATER CERTAINLY ACTS BETTER THAN ANY EXTEMPORANEOUS SOLUTION of THE LITHIA SALTS, and is, moreover, better borne by the stomach. I also often prescribe it in those cases of CEREBRAL HYPERÆMIA resulting from OVER MENTAL WORK—in which the condition called NERVOUS DYSPEPSIA exists—*and generally with* MARKED BENEFIT."

DR. WM. B. TOWLES, Professor of Anatomy and Materia Medica, in the Medical Department of the University of Virginia.

"BUFFALO LITHIA SPRINGS, No. 2, belongs to the ALKALINE or, *perhaps, to the* ALKALINE SALINE Class, *for it has proved far more efficacious in many diseased conditions than any of the simple* ALKALINE waters.

"*I feel no hesitancy whatever in saying that in* GOUT, RHEUMATIC GOUT, RHEUMATISM, STONE *in the* BLADDER, and in all diseases of URIC ACID DIATHESIS, *I know of no remedy at all comparable to it.*

"*Its effects are marked in causing a disappearance of* ALBUMEN *from the urine. In a* single case of BRIGHT'S DISEASE *of the* KIDNEYS, I witnessed *decided beneficial results from its use, and from its action in this case I should have great confidence in it as a remedy in certain stages of this disease.* In DYSPEPSIA, especially that form of it in which there *is an excessive production of* ACID *during the process of nutrition*, in some of the PECULIAR AFFECTIONS *of* WOMEN, notably in SUPPRESSION of the MENSES, and in CHRONIC MALARIAL POISONING, etc., I have found it highly efficacious."

DR. G. HALSTEAD BOYLAND, late Professor of Surgery, Baltimore Medical College, late Surgeon French Army (Decorated), Member Baltimore Academy of Medicine, Member of American Medical Association.

"In BRIGHT'S DISEASE of the KIDNEYS, ACUTE or CHRONIC, BUFFALO LITHIA WATER, Spring No. 2, is, in my experience, *without a rival*, whether in the PARENCHYMATOUS form or INTERSTITIAL NEPHRITIS. In cases in which the ALBUMEN in the URINE reached as high as 50 per cent., I have known it under a course of this water gradually diminish and finally disappear, at the same time other alarming symptoms were relieved and the sufferers restored to health.

"In STONE in the BLADDER of the RED LITHIC ACID and the WHITE PHOSPHATIC DEPOSIT, the SOLVENT power of this water is *unmistakable*."

Water in cases of one dozen half gallon bottles, $5.00 f. o. b. here.

THOS. F. COODE, Proprietor, BUFFALO LITHIA SPRINGS, VA.

of places have been changed or corrupted, it is deemed advisable to keep the altered appellations rather than to attempt to restore original spellings and pronunciations. Where the same name appears with various spellings—for example, "Allegheny," which is applied with varying orthography to a range of mountains, a county, a river, and so on—the different spellings are to be regarded as distinct titles, no attempt being made to produce uniformity. When a choice is offered between two or more names for the same locality, the one that is most appropriate and euphonious will be chosen. As a rule hyphens will be done away with, each compound word being made single. Two words will be made one wherever it is possible, "Rock Ledge" becoming "Rockledge," and so forth. The possessive form will be done away with when practicable, apostrophes being wiped out. Foreign geographic names, as to their spelling and pronunciation, will be determined by the Board in accordance with the same principles. All such designations as apply in countries that use the Roman characters will be given in the form adopted by the nations having jurisdiction, except when there are English equivalents already fixed by usage. There is no use in calling Rome "Roma" on an American map, or Vienna "Wien." As for names in languages that do not employ Roman characters—Russian or Turkish or Chinese, for example—they will be rendered according to a system already adopted in Europe, which approximates results by giving to each Roman letter one definite sound, using English consonants and Italian vowels. This method, of course, only approaches the correct pronunciations, but it is uniform. It must be understood that the Board is not organized for the purpose of hunting up reforms to make. It merely decides questions of propriety in spelling and pronuncation when appealed to. The various departments of the Government are constantly in need of accurate information in such matters, and official as well as personal requests for instruction from all parts of the country require frequent attention.

Exhaustion

Horsford's Acid Phosphate.

The phosphates of the system are consumed with every effort, and exhaustion usually indicates a lack of supply. The Acid Phosphate supplies the phosphates, thereby relieving exhaustion, and increasing the capacity for labor. Pleasant to the taste.

Dr. A. N. KROUT, Van Wert, O., says:
"Decidedly beneficial in nervous exhaustion."

Dr. S. T. NEWMAN, St. Louis, Mo., says:
"A remedy of great service in many forms of exhaustion."

DESCRIPTIVE PAMPHLET FREE.

RUMFORD CHEMICAL WORKS,
PROVIDENCE, R. I.

BEWARE OF SUBSTITUTES AND IMITATIONS.

CAUTION:—Be sure the word "Horsford's" is *printed* on the label. All others are spurious. Never sold in bulk.

BUSINESS NOTES.

HORSFORD'S ACID PHOSPHATE

For sunstroke. It relieves the prostration and nervous derangement. Dr. H. C. McCoy, Algona, Ia., says: "I have used it in cases of dyspepsia, nervous exhaustion and wakefulness, with pleasant results. Also think it of great service in depressed condition of the system resulting from biliary derangement.

AIR NAVIGATION.—Mr. Renard, the distinguished French aeronaut, is building a new dirigible air ship of over 3,000 cubic yards capacity. It is said that the motor is made of aluminum and operates perfectly. The balloon will soon be finished and will be tested shortly. It will leave Meudon and manoeuver between Versailles and Paris.

CLEANLINESS AND CIVILIZATION.—No normal type of man could flourish in a sewer, and no civilization makes headway where soap is scarce and impure air inflates the human lung. Crime, like a maggot, has ever fattened on such impurities, and the ominous discontent of the present age is the most intense where the sanitary laws are the least regarded. On the line of this indisputable verity civilization constructs its sewers, regulates the sanitary conditions of school houses and prisons, and, as a continuance of the same good work, has started the crusade against the chimney.

STOUT WOMEN'S DRESS.—The stout woman is always asking what she shall wear, says an exchange. Now these are some of the things she should not wear: She should not wear a tailor-made suit fitting her figure closely; it brings out every pound of flesh for the benefit of lookers-on. She should not wear a rosette at her belt, either at the back or front; it makes her look thicker through. She should not wear a lace or ribbon ruff about her neck, though the soft feather one is permissible if it have long ends. She should not wear a short skirt; it gives her a queer, dumpy look that is specially undesirable. She should not wear her hair low on her neck; it should be high and arranged with great smoothness, though it need not look oily. She should not wear a string of beads about her neck, rings in her ears, or, if her fingers are short and fat, many rings on them.

SCARING THE CONSCIENCE.—Of all her curious customs London cannot boast of a more singular one than that formerly so strictly adhered to at Holland House, one of the most historic old mansions in the British capital. The last of the lords Holland shot himself during a fit of despondency; everything pointed to a clear case of self murder, yet the Holland family could never be dissuaded from the notion that the old man had been murdered by some unknown assassin. Accordingly every night for years it was the custom for one of the family to go to the rear of the house punctually at eleven o'clock and fire a gun, for the purpose, it is said, of "scaring the conscience" of the murderer. This curious practice is a relic of mediæval days in continental Europe, and the case in point is probably the only instance where it has been noticed since the days of the Crusades.

PATER FAMILIAS.—Lucas Negreiras Paez left his home in Spanish Gallicia 72 years ago, to seek his fortune in America. A few weeks ago he returned to Spain to pass the rest of his life. He landed at Barcelona with his whole family, which consists of 16 daughters, of whom 6 are widows, 9 are married, and 1 is single; 23 sons, of whom 4 are widowers, 13 are married, and 6 are single; 34 granddaughters, of whom 3 are widows, 22 married, and 9 single; 47 grandsons, of whom 4 are widowers, 26 are married, and 17 are single; 45 great granddaughters, of whom 2 are married and 43 are single; 39 great-grandsons, all single; 3 great-great-grandsons, and 72 sons-in-law and daughters-in-law. In all it is a family of 279 persons. This great-great-grandfather was married three times and has had 39 children, 9 of whom appeared in pairs. The first born is 70 years of age, and had 17 sons, the eldest of whom is 54 years old, or 44 years older than his uncle, the last born son of the old man Paez. The head of this family is 93 years old and still hearty. He is erect, broad-shouldered and alert. He is a steady smoker and drinks wine moderately. He has a large fortune and is said by the Barcelona dailies to own a great hide and leather establishment in Boston. His whole business is managed by him and his sons. The ship in which the family was transported to Barcelona is the property of the father of all, and is commanded by one of his grandsons.

ORIGINAL. NO. 41.

Strawberry Cottage Pudding.

BY MRS. DEARBORN,
Principal Boston Cooking School.

Cream ¼ cup butter; add ¾ cup sugar gradually, beating all the time; then add 1 egg beaten till thick and light. Mix together a generous pint of pastry flour and 2 tea sp. Cleveland's Baking Powder; add this to the first mixture alternately with one cupful of milk.

Beat well together, pour into a buttered baking-pan and bake about thirty minutes in a moderate oven. Cut in squares and serve with stewed and sweetened strawberries and cream. (Copyright, 1891, by Cleveland Baking Powder Co.)

Use only Cleveland's baking powder, the proportions are made for that.

An even teaspoonful of Cleveland's Baking Powder does as much as a heaping teaspoonful of others. A large saving on a year's bakings. Try a can, Cleveland's.

PURE PEPSIN

In Powder and Scale.

MANUFACTURED BY

ARMOUR & COMPANY, Chicago.

Guaranteed free from adulteration or make-weights; of excellent physical properties and high digestive power.

Under similar conditions, **ARMOUR'S PEPSIN** will exhibit greater activity than any other pepsin now before the profession.

The Manufacturers will be pleased to supply members of the Medical Profession with samples of their pepsin, and with full details regarding digestive strength, if desired.

SEE PAGE 296 FOR VALUABLE OFFER.

WATCHES.

EVERY one wants a watch, and naturally a good watch that keeps accurate time, presents a handsome appearance, and is inexpensive. If such a watch can be found of American manufacture, it is an additional appeal to our patriotism. Just such a watch as this ideal THE ANALYST PUBLISHING COMPANY is enabled to offer as a Premium to its readers. Having some large advertising contracts we have been enabled to procure the movements of the manufacture of the best known American watch factories, namely, the Waltham, Elgin, Hampden and Illinois Watch Companies. These movements are adapted for both ladies' and gentlemen's watches, and are warranted by the makers. These movements have seven jewels, patent lever movement, chronometer balance, patent safety pinion, sunk hard-enameled dial, straight line visible palette, stem winders, hand set; in fact, contain all the latest improvements and can be readily cleaned or repaired by any ordinary good watchmaker. They can be regulated to run as close as any movement.

It is needless to say that to case these movements in solid gold cases would make them too expensive, yet they are cased in what are known as gold filled or stiffened "Ladd" cases, and are warranted to be 14 karat gold, made from two sheets of 14 karat gold overlaying fine composition metal, with regular jointed caps, covers and bezels, and to wear at least five years. They are not plated, nor rolled gold, but actual 14 karat gold cases, thin of course, but stiffened and strengthened by being filled with this fine composition metal. They are finished in the same manner, engine turned and engraved as solid gold watches, and wear and look just the same. No one but an expert can tell them from a solid gold watch. These watches are made both open face and hunting case style, in gentlemen's or ladies' sizes. For gentlemen we recommend plain engine-turned cases; for ladies, a handsomely engraved case.

How to Obtain One of these Watches.

These watches are not to be purchased from us at any price. Send us a club of 25 subscribers to the AMERICAN ANALYST, and $25, the regular subscription price, and one of these watches (your choice of style and size) will be immediately forwarded, post-paid and registered, to your address. You need not wait until you have your 25 subscribers all together, but forward them as you get them and they will be credited to you, and when the number is complete the watch will be sent. A subscription for two or three years will be counted as two or three subscribers.

As these watches are retailed by jewelers at not less than $25, it will be seen that we are offering a real premium with the sole object of increasing our circulation, and that by taking advantage of our offer any one can obtain a good, reliable and handsome watch without cost. As the number of these watches at this price is limited, it is advisable to take steps at once to procure a bargain.

BICYCLES

GIVEN AWAY TO BOYS AND GIRLS!

AN OPPORTUNITY OPEN TO ALL.

The Analyst Publishing Company being desirous of largely increasing their subscription list, will furnish every one with a beautiful Safety Bicycle, ABSOLUTELY FREE, in return for a few hours' canvassing.

To every boy and girl who secures 75 subscribers for the American Analyst at $75, we will give a splendid

$40.00

NONPAREIL

SAFETY BICYCLE.

These bicycles are adapted in size to boys, but are strong enough to carry a man. A boy's bicycle should be a strong one. They are manufactured by the OVERMAN WHEEL CO., the makers of the celebrated VICTOR Bicycle, and have the full guarantee of the makers.

The following is a brief description of the NONPAREIL SAFETY; 26-inch wheels; ball bearing all around, including pedals; solid crescent rims; double tangent spokes; three-fourths inch tires; cranks, three throw, $4\frac{1}{4}$ to $5\frac{3}{8}$ inches; guards to both wheels; tool-bag, oiler and wrench. Finished in bright enamel, all exposed metal heavy nickel-plate on copper.

In selecting these machines as a premium, we have disregarded cheapness and selected a Bicycle which is serviceable, and the makers of which have an established reputation for building the best Bicycle that money, machinery and brains can produce. We are actually furnishing the Bicycles and Papers at less than cost, but hope by stimulating active and successful canvassing, and thus enlarging our subscription lists, to make an eventual profit. We positively guarantee these bicycles to be just as here represented. They will be shipped by express f. o. b. in New York.

Subscription orders must be made out plainly and legibly, and sent as fast as secured, addressed to

BOSTON HAY AND STRAW MARKET.

Hay, choice to fancy, in large bales	$15.00 to $15.50
Hay, choice to fancy, perpetual pressed bales	14.00 to 15.00
Hay, fair to good	13.00 to 14.00
Hay, poor to ordinary	11.00 to 13.00
Hay, Clover and Clover mixed	10.00 to 12.50
Hay, swale	8.50 to 9.00
Straw, Rye, good to prime	17.00 to 18.00
Straw, Oat	8.00 to

BOSTON, June 13, 1891.

Receipts for the week are 368 cars of Hay and 42 cars of Straw; corresponding week last year, 231 cars of Hay and 25 cars of Straw. Receipts continue liberal and stocks have accumulated slightly. We quote the market firm but quiet. While the present crop prospects are so uncertain, receivers are unwilling to shade prices; at the same time with the present heavy receipts it is not possible to advance them. Some cars of strictly fancy hay in large bales are still selling at $16 per ton. Rye straw is easier with receipts in excess of the demand.

GRAND PREMIUM OFFER!

A SET OF THE

WORKS OF CHARLES DICKENS,

In Twelve Large Volumes,

Which we Offer with a Year's Subscription to this Paper for a Trifle More than Our Regular Subscription Price.

CHARLES DICKENS.

Wishing to largely increase the circulation of this paper during the next six months, we have made arrangements with a New York publishing house whereby we are enabled to offer as a premium to our subscribers a **Set of the Works of Charles Dickens,** in **Twelve Large and Handsome Volumes,** with a year's subscription to this paper, for a trifle more than our regular subscription price. Our great offer to subscribers eclipses any ever heretofore made. Charles Dickens was the greatest novelist who ever lived. No author before or since his time has won the fame that he achieved, and his works are even more popular to-day than during his lifetime. They abound in wit, humor, pathos, masterly delineation of character, vivid descriptions of places and incidents, thrilling and skillfully wrought plots. Each book is intensely interesting. No home should be without a set of these great and remarkable works. Not to have read them is to be far behind the age in which we live. The set of Dickens' works which we offer as a premium to our subscribers is handsomely printed from entirely new plates, with new type. The twelve volumes contain the following world-famous works, each one of which is published *complete, unchanged, and absolutely unabridged:*

DAVID COPPERFIELD,
MARTIN CHUZZLEWIT,
NICHOLAS NICKELBY,
DOMBEY AND SON,
BLEAK HOUSE,
LITTLE DORRIT,
OUR MUTUAL FRIEND,
PICKWICK PAPERS,
BARNABY RUDGE AND CHRISTMAS STORIES,
OLIVER TWIST AND GREAT EXPECTATIONS,
THE OLD CURIOSITY SHOP AND THE UNCOMMERCIAL TRAVELER,
A TALE OF TWO CITIES, HARD TIMES AND THE MYSTERY OF EDWIN DROOD.

The above are without question the most famous novels that were ever written. For a quarter of a century they have been celebrated in every nook and corner of the civilized world. Yet there are thousands of homes in America not yet supplied with a set of Dickens, the usual high cost of the books preventing people in moderate circumstances from enjoying this luxury. But now, owing to the use of modern improved printing, folding and stitching machinery, the extremely low price of white paper, and the great competition in the book trade, we are enabled to offer to our subscribers and readers a set of Dickens' works at a price which all can afford to pay. Every home in the land may now be supplied with a set of the great author's works.

OUR GREAT OFFER

TO SUBSCRIBERS

TO THE

AMERICAN ANALYST.

We will send the **ENTIRE SET OF DICKENS' WORKS,** *in* **TWELVE VOLUMES,** *as here described, all postage prepaid by ourselves, also* **THE AMERICAN ANALYST** *for* **ONE YEAR,** *upon receipt of* **$1.50,** *which is only* **50** *cents more than the regular subscription price of this paper.* Our readers, therefore, practically get a set of Dickens' works in twelve volumes for only **50** cents. This is the grandest premium ever offered. Up to this time a set of Dickens' works has usually been $10.00 or more. Tell all your friends that they can get a set of Dickens' works in twelve volumes, with a year's subscription to **THE AMERICAN ANALYST** for only **$1.50.** Subscribe now and get this great premium. If your subscription has not yet expired, it will make no difference, for it will be extended one year from date of expiration. We will also give a set of Dickens', as above, free and post-paid, to any one sending us a club of three yearly subscribers.

Tabasco Pepper Sauce

OR LIQUID PEPPER.

Is simply the Pulp of the Ripe Pepper Extracted by Pressure.

The seed of this Pepper was obtained from Central America, and by careful cultivation in Louisiana for many years has been so improved in strength, flavor and aroma, as to have become a new variety of Red Pepper, superior to all others. The pulp is so handled as to retain all the flavor, strength, aroma and color of the ripe fruit, and to keep unimpaired in any climate. It excites the appetite, promotes digestion, and is pronounced, by connoisseurs, to be the finest condiment in the world. For medicinal purposes it recommends itself by its purity, strength and diffusible form.

Manufactured by E. McILHENNY,

NEW IBERIA, LA.

For Sale by all Wholesale Grocers.

To Subscribers, Readers and Advertisers.

SUBSCRIBERS' attention is called to the great variety of interesting and instructive subjects treated in this number. We respectfully ask the co-operation of our subscribers in extending our Subscription list, which will enable us still further to increase the value of the AMERICAN ANALYST to them.

The CASUAL READER is specially requested to examine our liberal premium offer.

ADVERTISERS who do not know of this Journal already, are respectfully referred to article headed "A Business Benefit."

ALL are kindly requested to peruse this number thoroughly.

The AMERICAN ANALYST can be had at any news stand in the United States. Any newsdealer will take orders for it, the American News Company being our wholesale agents. All postmasters will receive subscriptions.

NATRONA BI-CARBONATE OF SODA.

(ABSOLUTELY PURE.)

The nature of the raw material from which NATRONA BI-CARBONATE OF SODA is made—viz., kryolith, a mineral containing *pure sodium*—insures a purity and uniformity of product which cannot be obtained from any other known material. In making BI-CARB. SODA from any other raw material, the use of sulphuric acid is a necessity, but none is used in any part of the process of making NATRONA BI-CARB.; hence its entire freedom from the slightest trace of arsenic, which is always present in ordinary soda. Its absolute purity and entire freedom from all traces of *sulphate of soda*, common salt and other impurities, render NATRONA BI-CARB. NEARLY TASTELESS, and being bolted through the finest bolting-cloth, insures the finest stage of division.

To these indisputable facts the attention of CONSUMERS of soda is specially called. They are IMPORTANT, and should influence both those who use and those who sell soda, to buy and sell NONE BUT THE BEST.

The NATRONA BI-CARB. Soda is kept in stock by almost every wholesale druggist and grocer throughout the United States, of whom it may be ordered.

Natrona Bi-Carb. Soda is unequaled by any other brand of English or American Manufacture.

INSTRUCTIONS TO SUBSCRIBERS.

The **Names of all Subscribers** are registered as soon as received, and paper is always promptly forwarded.

Postage.—The postage to all parts of the United States and Canada is paid by the publisher.

Remittances of small sums may be made with comparative safety in ordinary letters. Sums of one dollar or more must be sent by registered letter or P. O. money order, otherwise we cannot be responsible for same. Silver must not be sent in a letter.

Postage Stamps will be received for the fractional part of a dollar, and in any amount when it is impossible for patrons to procure bills, but you must send one or two-cent stamps only.

SUBSCRIPTIONS.—The AMERICAN ANALYST will be sent one year to any subscriber for ONE DOLLAR. New subscriptions can begin at any time.

We Stop the Paper at the expiration of the time paid for unless a renewal of subscription is received. Those whose subscriptions have expired must not expect to continue to receive the paper unless they send the money to pay for it.

Change of Address.—Subscribers wishing their addresses changed must invariably give their former as well as new address.

Missing Numbers.—It occasionally happens that numbers of our paper sent to subscribers are lost or stolen in the mails. In case you do not receive any number when due, write us a postal card and we will cheerfully forward a duplicate of the missing number.

Most Important of All.—In every letter that you write us, never fail to give your full address, plainly written—name, post-office, County and State.

Address all letters to

ARSENICAL POISONING

Repeated efforts have been made in Massachusetts to have an amendment passed to the adulteration of food and drugs act forbidding the use of arsenical coloring in wall paper, carpets, hangings, textile fabrics, and particularly on children's toys, and boxes to hold confectionery. The committee appointed by the legislature recommended a postponement of nearly the whole subject for further investigation under the direction of the State Board of Health. The committee recommended placing immediate prohibition on the use of poisons in children's toys or confectionery, but declined to go further at present. Since then a minority report from the same committee was presented in which three members dissent from this merely tentative action, assigning the following reasons: They recite the fact that the petitioners, 2,352 in number, of whom 1,207 are physicians, including a large majority of leading members of the profession in Massachusetts, ask only for the same protection now afforded against the adulteration of drugs and food, a protection similar to that afforded in France, Germany, Austria, Bavaria, Denmark, Holland, and other countries. No remonstrance was received except from dealers in wall paper and an expert from this city and his former associate, and one gentleman interested in apartment houses, where the papers were compained of. Not a single, other citizen, manufacturer, expert or physician appeared before committee, they say, to object to the passage of the proposed bill, and no one at all appeared to object to limitation of the use of arsenic in fabrics. On the contrary, the largest manufacturer of textiles in New England, speaking for himself and others, said that they would be glad to have a reasonable and fair prohibitory law. The report then cites the facts brought before the committee regarding illness resulting from exposure to arsenic in paper and fabrics, the cases presented being too well attested, they say, and too serious, to be dismissed with ridicule. As a conclusion, therefore, the minority reported in favor of so amending the law concerning the adulteration of drugs and food as to include household articles contaminated with arsenic. It will be remembered that Prof. Chandler testified strongly against the proposed restrictions, he, doubtless, being the expert referred to in the report. Prof. Chandler, however, is a chemist, and not a physician. He naturally looks at the question from a chemical standpoint, and takes it for granted that manufacturers would carry out the full chemical manipulation of the arsenic, which is used in all these colors as the oxidizing agent. Had the learned professor given practical directions for the use of a cheap substitute for arsenic, such as caustic soda, in this oxidizing process, he would have solved the difficulty and obviated legislation. Physicians may reasonably be expected to know more of the causes of disease than chemists, and enough of them have testified from time to time in such a straightforward manner as to the dangers of arsenic in domestic use, as to render highly desirable its exclusion from such use. Of course to do this would cause trouble, and probably lessen the profits of manufacturers, but that such commercial considerations should be allowed to have any weight in matters concerning health is simply monstrous. Most persons who are acquainted with the character of arsenic would greatly prefer to take no chances with it. As manufacturing is now conducted they have practically no defence against the opinions, prejudices, or unscrupulousness of those who furnish the materials that they are obliged to use, and at the very least there ought to be provided some easy way in which people who are not partial to arsenic may know when it is being served to them and when it is not. Another great danger of these arsenical colors arises from the fact that the public generally mistakingly believes that the only poisonous color is green, when in fact the bright reds and several other colors which are extensively used in carpets, hangings, clothing, hosiery, etc., are far more dangerous. How this poison acts is not so well established as the fact that many people have been seriously injured in health by sleeping in rooms papered with arsenical paper, or furnished with arsenical carpets and upholstery.

CONDENSED CREAM ONCE MORE.

We have pointed out to our readers that the Helvetia Milk Condensing Co. of Highland, Illinois, is selling unsweetened condensed milk as "Condensed Cream," and that to keep it from fermenting they put this product through a sterilizing process which, as we clearly proved, so changed the character of the milk as to make it unfit for many uses. These statements have been strenuously and disingenuously denied by those who claim to speak for this company. In a late issue of the *Chicago Grocer* we find a descriptive article, evidently published in the interest of the Helvetia Company, as it contains an electrotype of the buildings of the company, in which there is a full corroboration of all of our statements. Speaking of the milk brought there in wagons it says:

"After heating it to a boiling temperature it is next introduced into vacuum cans, which apparatus are constructed of copper, holding probably a thousand or more gallons, and so arranged that the atmosphere may be entirely excluded. They are connected with air pumps by which the air in the pans is exhausted which enables the evaporation of the milk at a very low degree of temperature. When the milk is reduced to the proper consistency, it is a cream."

It is by this untrue statement that we charge the Helvetia Company with selling an article for what it is not. Milk cannot be condensed to make cream, and no one knows this better than the company which make such statements. The article then goes on: "Immediately after being filled the cans are "capped" and then conveyed to the "processing" room, where they are subjected to heating in large tanks. The object of the heating process is to destroy every living germ or micro-organism, harmful or not, which may be contained in the milk." It is this "processing" which breaks up the fat globules in the condensed milk and so changes its character that it is really not milk any longer. It may answer some purposes, but would be extremely dangerous for other purposes, such for instance as food for invalids or children.

FLATS AND SUNSHINE.

An almost complete change in the construction of metropolitan dwellings has been effected by the introduction of what are variously known as French flats, or apartment houses, and in New England as hotels. The primary object of constructing these buildings is to gain room by raising them higher. A five story tenement was at one time considered very high, but since the introduction of elevators nothing is now thought of

ten, twelve, fourteen and even sixteen story buildings. The question arises are these dwellings healthful? It is true that the various boards of health have prescribed certain rules according to which they must be built, but it would not be difficult to point out many vulnerable points, wherein these modern beehives, though amply provided with air space, are deficient in the equally important element of sunlight. We do not now speak of those so called flats in New York City, where by the addition of a vestibule door and a few yards of cheap oilcloth an avaricious landlord converts an ordinary tenement house into a "flat house" and thereby squeezes double rents out of unsophisticated tenants whose pride makes them willing to pay more to live in a flat than in a perhaps more commodious and cheaper tenement. Nor do we refer to the very high priced apartment houses which are more like family hotels than private dwellings. But we have in mind the medium priced flats and apartments where the rentals in New York and other large cities average from $40 to $100 per month. These are built with front and rear windows having the parlor in front and the kitchen in the rear, and these two are the only rooms in the apartments exposed to a direct sunlight. All the other rooms are between four walls and depend for light and air entirely upon so-called light and ventilation shafts. These latter are nothing more nor less than huge ventilation chimneys, and serve to average up all the foul air exhaling from the various abutting apartments. Even where the air in these shafts is pure and the light sufficient to do away with artificial lights on an average bright day, there is no sunlight. Put a flower in one of these inside apartments and it will fade and quickly die. The ventilation though ever so pure will not keep it alive. It needs sunlight to thrive. If a flower needs sunlight, how much more does a human being need it? Of course there are relative degrees in this absence of sunlight in modern flats, those higher up having more chance for the sun to reach them than those below which are surrounded by high buildings. But we assert, and we have the proof to satisfy us of the accuracy of our statement, that the lower stories of our modern flats are absolutely unfit for human habitation, excepting when they are situated on a street corner, and only ten per cent. of flat buildings in a large city can be so situated. Let those who dwell in these lower stories look back in their experience and say how the state of the health of their families, especially that of children, compares with that they enjoyed before they lived in these dark caverns where sunlight never enters. Let our boards of health examine their death statistics and say where deaths from zymotic diseases most often occur. Ask the physicians where disease is most stubborn and least readily yields to proper remedies. Not to mention the more serious ailments, how many of those who now dwell in these lower flats get up in the morning feeling feverish and lethargic, have aches in the head and limbs and feel the manifold symptoms of malaria? Surely it will not take much reflection to convince them that when they lived in the old-fashioned dwellings they were far more healthy. These flats are yet comparatively a novelty and experience will tell, but that experience may be dear.

PURE FOOD.

THE MANUFACTURERS PROPOSE TO HAVE A SHOWING ON THEIR OWN BEHALF.

At a meeting of Food Manufacturers, held in the Mercantile Exchange, New York, June 8th, with Mr. Reed Gordon, of Messrs. Gordon & Dilworth, presiding, the secretary was instructed to communicate with all those food manufacturers who aim to manufacture pure and wholesome food products of a fine quality only, and invite them to be present at the next meeting, with the view of joining this organization, to be known as the Food Manufacturers' Association of the United States. The object of which association is to encourage the manufacture of pure and wholesome food products, and to improve the quality and elevate the standard of food by every legitimate means; to enlighten the people as to the importance of using only the best quality of goods. It is believed by those interested in promoting this movement that such an association will contribute very much towards improving the quality of food products, and establish a pleasant and friendly feeling among the manufacturers of that class of goods, whose interests are identical, to the mutual benefit of all concerned. A committee appointed to draft a constitution and by-laws was composed of the following gentlemen: E. C. Hazard, chairman; Alphonse Biardot, of Franco-American Food Co.; Samuel W. De Coster, of Armour & Co.; E. C. Rich, of E. C. Rich & Co.; Townsend Cushman, of Cushman Bros. The secretary was directed to address a communication to the New York Retail Grocers' Association, inviting the members of that organization to co-operate with the food manufacturers in holding a food exposition in New York City the coming fall or early spring, whichever date may hereafter be agreed upon.

MOTHS.

A SEASONABLE DISCUSSION OF A MISERABLE PEST.

The great mistake folks make is to await the heat of summer before watching for moths. Artless young housewives look askance at the bare thought of bugs in their newly-built homes, but if they stop to squarely consider the subject, they must admit that visitors are at any time liable to bring in with their clothing a guileless moth, which, with good health and industry, can hatch hundreds of its kind in a week, and ruin everything of an animal texture with which its larvæ or grubs come in contact; therefore the need for serious watchfulness and a knowledge of the subject becomes apparent. One immediately protests, "But I have never watched specially for moths, and everything in the way of clothing and fabrics in my house has not been ruined." "True, but your immunity from depredation has been good luck—nothing more. The moth lays its eggs in dark places, and the grub which is hatched moves slowly, and its feeding spots are usually within a foot or so of its place of birth. If by good luck its place of birth is away from a textile fabric, the texture will not be hurt; if near, it is sure destruction." The quacks and "preventive" manufacturers have always reaped a rich harvest through the ignorance of people regarding the moth and its habits. Folks have bundled up their woolens and packed them away in their chests full of tarboline, or carboline, or cedarline, or camphorine, and actually believed that they would be safe until fall. They have wrapped up hundreds of moth eggs, which eventually hatch the grub. These odors will never kill a moth or destroy its life germs. To be sure a moth will not voluntarily seek a nesting place where the odor exists, but if boxed up with an odor it cannot escape from, it simply proceeds to lay its eggs in the atmosphere, which becomes a second nature to the grub when hatched. Anything saturated with arsenic, or creosote, or even salt, or impregnated with sulphur, the moth or worm will not touch, but the use of these articles is dangerous to the colorings of fine textures. It is discouraging, indeed, when a housewife shakes out her clothes and puts them in a camphor trunk and keeps them there all summer, to find that in the fall they are fairly riddled; but the trouble has been she watched only for moths, when the moth is not at all destructive. It is the worm that she should have been on the lookout for, which is hatched from the egg, and as the egg is hardly perceptible to the naked eye—a mere white speck like the point of a pin—it is often passed unseen. Until recently, the utmost confusion and ignorance prevailed regarding the nomenclature of the moth species, but it is now a clearly defined fact that there are three distinct species of wool-destroying moths common in this country, all of which are of European origin. To be scientifically correct, we should term them the Tinea pellionella, Linn.; the Tinea tapetzella, Linn.; and the Tineola biselliella, Hummel. The commonest species are light-brown and distinguished by spots. They begin to appear late in April and may occasionally be seen flitting about as late as August. They pair off, and the female then searches for suitable places for the deposition of her eggs, working her way into dark corners, crevices of the wall, cracks in the floor, or deep in the folds of garments, apparently choosing by instinct the least conspicuous places. The moth lays from eighteen to one hundred and forty eggs at a time. From these eggs hatch, in a period of from three to seven days the white soft body larvæ or worms, all of which begin immediately to make a case for themselves from the fragments of the cloth upon which they feed. The case is in the shape of a hollow roll, from a thirty-second to an eighth of an inch long. We have all noticed these "rolls" on fabrics and frequently we have crushed them, supposing that we have thus prevented all damage, when the very existence of the cylinder shows that the grub has already fed. As the worms grow, they enlarge this case by adding material which they get by feeding. The worm reaches its full growth in thirty-six days, and then crawling into some yet more protected spot remains torpid during the winter within its case, which by this time is thickened and fastened at either end and the full-sized cocoon. The transformation of the moth takes place within the case during the following spring. Such is the life round of the species. The worm feeds on woolen fabrics, curled hair, hair-cloth, furs, feathers or anything of that character which may possess an animal deposit, for within the cellular tissues of hair there is the same nutriment which one finds on a smaller scale within a bone. It is the thirty-six day period, from the time that the eggs are laid to the time that the worm or grub reaches the full size, that the damage is done, and it is fortunate that all of the eggs that are laid do not hatch—in fact, but a small proportion ever find life. The second species constructs its cocoon mainly from fragments of the material upon which it has been feeding, spinning a certain amount of silk, however, wherever it goes, leaving the trace which one sometimes finds on woolen fabrics. This species is most common from Washington southward. The parent moth is of a dark straw color, and has none of the spots on it that you see on the Tinea pellionella. The moth of the Tinea tapetzella, the third species, is readily distinguished from all others by the front wings, which are black from the base to the body and white beyond, the white portion being sometimes crowded with dark-gray. The habits of these species are much the same, with the exception that the larvæ or worm of the last named is most destructive, using for its cocoon cylinder pieces of the cloth itself on which it is feeding. It must be now apparent to the careful reader that it is quite difficult to kill the infinitesimally small eggs by reason of their almost imperceptible diminutiveness and difficult also to eradicate the moth by reason of its secretive habits. A benzine spray is sure death, but there are many objections to its use and danger from its inflammable character; still, if the ordinary throat spray, which can be bought for a trifle, is filled with benzine, and the vapor thrown into crevices against moth or eggs, it will destroy them, but no light should be brought into a room thus treated, until after it has been thoroughly aired and the odor dissipated. After a thorough airing of a woolen fabric, for the purpose of driving out any concealed moth (for a moth abhors light), and after time has been given to the development of any concealed egg, you may be reasonably sure that there is nothing harmful on the fabric; then it is as safe done up in a paper parcel as

it would be if saturated and buried beneath all antimoth remedies in existence. Camphor, tobacco, naphthaline and other strong odorants are only partially repellent to the flying moth, and have no effect at all upon the eggs or the worm, which is the destroying element. The benzine spray is the least objectionable destroying agent that we know of. It may be used very safely upon carpeting, but the utmost care should be exercised in using it on fabrics of a delicate character. One should not confuse the moth with the carpet beetle. Frequently housekeepers discover their carpets eaten and they attribute it to moths; indeed, the carpet beetle is frequently called the buffalo moth. The perfect beetle is three-sixteenths of an inch long, and when disturbed it draws its legs and feigns death. It is white, black and scarlet, the scarlet being confined to a stripe down the middle of the back. It begins to appear in the fall, and soon the species pair off and the female deposits her eggs upon the carpet itself, and not in the cracks and crevices, as generally supposed. During the daytime these beetles frequently fly to the windows, and may be caught there, but they seldom leave the house until their eggs have been deposited. The treatment is similar to that with moths.—*Upholsterer.*

AIR.

HOW WHIRLWINDS, WATERSPOUTS, AND CYCLONES OCCUR.

(*Continued from page* 269.)

The winds described in the previous number may be regarded as aerial currents. Originating in the unceasing but vain effort of the heated equatorial air, and the cooler polar air to attain an equipoise, they finally describe a great circle, which may be regarded as the normal condition of the atmosphere. This normal condition is, however, subject to many disturbances through the agency of locally originating whirlwinds, in which the air revolves in a circle forming columns nearly perpendicular to the earth's surface. The simplest and best known of these phenomena are the harmless whirlwinds which, on hot days, originate over the heated surfaces of roads, or other bare surfaces, whirling straw, leaves and dust, and bearing them upward. G. Von Rath describing a waterspout which he witnessed at Bonn, June 10th, 1858, writes as follows: "After long waiting in vain for any sign of rain, heavy thunderclouds were seen advancing from the south towards noon of the 10th of June. About one o'clock we saw in the same direction a pillar of whirling dust rising to a height of at least 700 metres. When the whirlwind reached the Rhine, the water over a circle of about fifty yards was lifted up, and the spray and foam on its surface was caught up into the whirlwind. Out of the blue-gray thundercloud stretched down a yellowish-white skittle-shaped point of cloud, until it touched the dust pillar, which had now reached the left bank of the Rhine. The whirlwind now sprang back upon the Rhine: the water was lashed to seething, whirling foam; and presently out of the foam a column of water reared itself almost perpendicularly. The column was divided into three shafts, which pursued their upward course parallel to each other, in the direction of the descending cloud point; the ascending and descending columns united, and the water was borne into the clouds, which were floating much higher than the Drachenfels. The waterspout resembled at first a Gothic tower, but as its foot reached some shallows in the Rhine it contracted to a giant obelisk, advancing towards the southern foot of the Drachenfels, which it did not reach, as the commotion in the water was only of short duration. The whirlwind, after lasting about half an hour, ended with a terrific downpour of rain. The course of the whirlwind was marked by fallen tiles, strewn branches of trees, and the cereals lodged so that the stalks in the middle of the course, which was about fifty yards wide, lay parallel to it, while those on the outer edges of the course were inclined towards the centre." The ocean waterspouts are of larger size, extending sometimes to a diameter of sixty metres, especially in the tropics. Rye attributes their origin to a fluctuating equilibrium of the atmosphere. When the temperature of the air falls more than one degree for every hundred metres of elevation, an ascending current of air starting from a stratum of equal density is accelerated in its course, ascending faster than it parts with its heat, so that it is always warmer than the strata through which it passes; but should it fall only a little below the temperature of the strata through which it is passing, it sinks downward with ever-accelerated speed. The conditions for a fluctuating equilibrium exist when a vapor-laden ascending current experiences a fall of temperature of only one-third of a degree for a hundred metres of elevation. Moist air ascends more lightly than dry air, for the heat set free by the condensation of vapor in its ascent expands the air and increases its buoyancy. Towards the partial vacuum created at the base of the ascending air current, the adjacent air masses rush in on all sides with increasing force, and are drawn upward long before they can reach the calm centre at the base of the column. The watery vapor is condensed into fog; out of a rapidly growing cloud there sinks a second funnel-shaped column, which unites with the first, and you have the waterspout. On the warm tropical ocean, under the influence of the sun's rays, over a broad area, the conditions favoring a fluctuating density of the atmosphere readily arise. Very little disturbance may suffice to promote the ascent of voluminous masses of vapor-laden air, which give off their vapor as they ascend, and by the liberation of its latent heat cause the expansion of the air, and thereby accelerate its upward course. Under the ascending aerial masses, the pressure naturally diminishes, causing a barometric minimum, with a fall extending to 700 mm. Encircling this calm region of aerial ascent, there is a pressure of the atmosphere from all sides, and the air would rush directly towards the centre, were it not for the earth's motion. But as the earth revolves from west to east, the aerial currents are subject to a deflection, to the right in the Northern, to the left in the Southern Hemisphere. As a consequence, the currents from north and south instead of taking a direct course to the centre are compelled to revolve around it in a spiral course, which in the Northern Hemisphere is from north *via* west, to south and east, that is, contrary to the movements of the hands of a clock, while in the Southern Hemisphere the currents pursue an opposite direction. Centrifugal force prevents the centre from being reached, so that the motion of the air currents is almost circular. The revolving currents whirl around the central column of attenuated air, pursuing a spiral course upward, and thereby increase the tenuity at the centre, and tend to perpetuate it. On the Equator itself, as indeed anywhere between 5 deg N. lat. and 5 deg. S. lat., cyclones cannot arise, because the deflecting influence of the earth's revolution at the centre is so inconsiderable, there being no spiral movement within the area of the least atmospheric resistance. An attenuated column cannot, therefore, exist very long, being subject to the pressure of the direct instreaming lateral currents. These currents operate in the equatorial regions approximately under 10 deg. N. or 10 deg. S. lat. The middle point of a whirlwind advances with a speed which, with the West Indian cyclones, reaches from 25 to 35 kilometres an hour, and further north to 80 kilometres. In the Indian Ocean the whirlwinds move more slowly—5-20 kilometre. In the North Atlantic Ocean the course of the centre of the whirlwind, within the tropics, is towards the northwest, but between 20 and 30 deg. N. lat., that is, on the confines of the trade winds the course is deflected, the currents taking a northeasterly direction to the temperate zone. In the Southern Indian Ocean the storm centres pursue a southwesterly course within the tropics and a southeasterly direction in the south temperate zone. This is accounted for as follows: In a whirlwind originating in the region of the northeast trades the air circles from north *via* west to south and east. The northeast tradewind antagonizes the southeasterly portion of the whirlwind and decreases its speed, while it expedites the course of the northwesterly. In the southeast the air is rendered more dense; in the northwest, on the contrary, it is attenuated. As a consequence of the unequal pressure on the original centre, that centre is deflected towards the side on which the pressure is least, that is towards the northwest. But on leaving the region of the northeast trades this deflection ceases. The southern air has then greater centrifugal force for its increase of speed than the northern cool, dry air of the temperate zone, which originates in the northwest and flows through the southwestern half. A lively acceleration of speed, along with an appreciable attenuation, will now take place in the northeast point of the whirlwind. The centre of least pressure will consequently be deflected toward the northeast, and the centre of the whirlwind must necessarily follow this direction. Similar investigations have determined the course of the storm centre in the Southern Hemisphere. The right side of the cyclone is especially feared by sailors because the wind-driven ship is inevitably driven towards the point on which the storm centre is advancing and the hurricane is strongest. To get out of a cyclone a sailing vessel in northern latitudes must keep its starboard side to the wind, but be careful to keep outside the 'dangerous quarter.'"

A DOLLAR A MINUTE.—One dollar a minute is the charge for using the new telephone line between London and Paris. Distance about 280 miles. Forty cents a minute is the price between New York and Washington, about 240 miles.

BEARDS AND NATURE.—Philadelphia is still agitated over the Sunday shaving question. On this subject, Henry Labouchere has something to say in London *Truth*, viz.: "Had Providence intended that there should be no shaving on the Sabbath day, Providence would presumably have prevented beards from growing on that day. We allow cows to be milked on Sunday, in deference to the cosmic laws which cause the animals' udders to fill on that day. Why not show equal respect for the laws under which our beards grow?"

EARNEST LADIES.—In order to help keep Pittsburg streets clean the Ladies' Health Association of that city propose to send a paper, in the form of a pledge, to each householder and business man, and ask them to sign it and return it to the secretary of the association. The paper will ask that each one will have the sidewalk in front of their residence or place of business swept early in the morning, and no rubbish shall be swept therefrom into the street; the ash barrel shall be put out at the proper hour and taken in as soon as emptied; to prevent dust the ash barrels will be sprinkled; papers are not to be mixed with the ashes nor thrown into the street; nor will banana or orange skins be thrown into the street or on the sidewalk. The persons also pledge themselves to be watchful of the general condition of the streets, and all things noticed which are detrimental to the cleanliness or health of the city will be reported to the society.—*Sanitary News.*

AMERICAN TRUSTS.—Mr. Plimsoll, a member of the English Parliament, in an article in the *Nineteenth Century*, has discovered that in the United States no less than seventy-one large combinations were organized in 1888-89 Some of these include many others, in all 490 "trusts" were organized in two years. They have been formed to control almost every branch of industry, including the manufacture of paper bags, coffins and pickles, and it is computed they include no less than $2,000,000,000, or considerably more than two-thirds of the entire manufacturing capital of the United States. Mr. Plimsoll is afraid that further attempts will be made to foster and develop this odious trust system in England, and he urges her legislators to rouse themselves promptly to the danger of this fearful menacing calamity. He suggests that a select committee or a royal commission should be constituted without loss of time, "to inquire into the whole of the subject."

ICE.

NATURAL OR ARTIFICIAL, WHICH?

Ice at all seasons of the year has become a necessity and is now more than a luxury. In large cities it is required for many purposes almost indispensable for man's very existence. The butcher needs it to preserve his meat, the hotel keeper depends upon it to keep his provisions, every family must have it to prevent the daily food from spoiling; fish and poultry dealers and shippers, dispensers of all kinds of beverages, the ice-cream maker, dealers in butter, eggs and cheese, cold storage warehouses, brewers, and even the undertaker have to rely upon ice to enable them to carry on their business. The only question is what kind of ice to use, natural or artificial. If both are to be had at the same price, which is the best? As artificial ice has but lately come into the market as a commercial competitor with natural ice it has exerted a powerful influence in fixing prices. In New York City especially, where the dealers in natural ice, aided by an open winter and a hot summer, by dint of an unscrupulous combination had succeeded in fixing exorbitant prices upon their commodity, the introduction of artificial ice has been a boon to the consumer. Naturally the old ice companies, seeing their business taken from them, resorted to misrepresentations about the artificial product. Some of these misstatements are so preposterous that they indicate to a thinking reader that the icemen are of a very low order of intelligence, and consequently believe that the general public can be easily imposed upon by the silliest stories. Some of these canards are really funny, for instance, that artificial ice will turn meat black, that it does not give within fifteen or twenty degrees of the cold given by natural ice, that the ammonia circulating in the pipes through the brine tank leaks and, with the lubricating oils used, is deposited in the centre of the artificial ice. This last assertion is the most preposterous, because, to enable the ammonia and grease to come in contact with the ice, there must be contact between the brine and ice, which would make the ice salty. To make this still clearer we will briefly describe the process of making artificial ice and compare it with natural ice, leaving the reader to judge which would be preferable. Croton water converted into steam, after being filtered once, then condensed—the process of distillation, which all the world knows is the best and only way of purifying water or any liquid—passes through charcoal filters, being reboiled to force out the air and comes forth freed of all impurities. The purified water is conducted into the galvanized cans and frozen in thirty-six hours into solid cakes of ice so clear that print may be read through cakes eleven inches thick. There are no tinctures from iron pipes—they are galvanized. There is no iron box, but a galvanized can. There is no ammonia in the ice; it is impossible for it to get there or freeze if it were there. There can be no greasy smell or taste in the manufactured ice, for the water it is made of passes through fifty feet of triple burned hardwood charcoal, and no impurity can pass through this. Using the extremes of temperature in steam and frost in pipes constructed to avoid all rust, also such careful and repeated filtering, there are no greasy compounds in the ice. A word regarding the sources of natural ice. The great supply of this city comes from the Hudson River, above the flow of the tides. The Hudson is here practically an open sewer, and people are being brought to face this fact. The drainage of the city of Albany, with a population of 150,000 people, of fifty factories; Troy with 60,000 people and thirty or forty manufacturing places, several other towns and adjacent farming districts, empties into the Husdon River. The ice thus gathers the abominations of city filth, which it freezes, for the theory that nature precipitates all impurities into the water below was long ago exploded, as almost any schoolboy knows. Then, too, while the ice is being harvested, it receives on its surface the added filth of from 8 000 to 10,000 men, and 800 to 1,000 horses that spend entire weeks on the ice fields. These facts will, we think, sufficiently answer those who seek to injure an industry that is increasing in strength and popularity, and has already proven its ability to take care of itself, and taught the natural ice companies that their day of high prices is gone. The ice from lakes like Mahopac, Greenwood, Rockland, etc., is very little, if any, purer than Hudson River ice, for if it should have less sewerage in it, the amount of decaying vegetable matter washed in from its surroundings more than makes up in unhealthy germs what it may lack in the other respect. To summarize, then, we ask the question: Ice, natural and artificial—which is the better? Sometimes one, sometimes the other, as to the conditions under which it is made. Ice from the pure inland lakes, ponds and rivers of Maine or the North, is better than from the Hudson or the impure lakes, ponds and rivers in this vicinity, as it is harder, more stable, and contains more cold per cubic foot, being made at a lower temperature. In a word, the purer and quieter the water, and the colder the place where it is frozen, the better the ice. Ice machines, as a rule, produce lower temperatures, more continuous and even, than Nature in this latitude; hence, if the water to be frozen, being pure, be put into clean iron cans or moulds, its absolute quiescence being secured and subjected to a temperature lower than that of Nature, the product will be better than Nature's. On the other hand, if the pure water of a northern lake, pond or river be frozen at a temperature below that of the machine, the ice will be better than the machine-made. In either case it is pure only as the water is pure, nothing being added or taken away in the process of freezing. The better the ice the slower it melts, and no refrigeration ensues without melting. But if quick results are desired, as in the making of ice-cream, the ice must be broken that greater surface may be exposed to the action of the salt. Since the well-constructed and well-managed modern ice machine deals in lower temperatures than Nature affords in this climate, and there is no possibility of contamination by materials used, it follows indubitably that the machine ice is the better; and if the object to be attained is the refrigeration of rooms, warehouses, etc., and not the actual making of cakes of ice, the machine will do it far better than Nature and at less than half the cost, and if pure, solid ice be required it will make it at a less cost than it can be cut and housed at any lake or river, even under the most favorable conditions of wages and weather.

BEAUTY AND TASTE.

HOW WOMEN CAN MAKE THE MOST OF THEMSELVES.

Color is paramount in beauty. Generally this maxim would be understood but in one way. By "color" the average woman understands a high pink flush in the cheeks. If she has not this sort of color she takes it for granted that she has none. According to the popular idea a pale woman, or a "washed-out" one, has no tints or semi-tints in her face at all. This is the gravest of mistakes. An artist finds a hundred gradations of color in a complexion that to the uninitiated eye seems merely white or sallow or uniform olive. And that artist, were he given free scope to garb the woman in question as he chose, would so manage every detail that indefinite harmonies of hues would become salient, and produce the best possible effect. Color should be studied by every woman who chooses to make the best of herself, immediately after contours. And often the study pays better for the trouble and forethought it entails. The outlines of face and figure, though they may be very advantageously modified, can never be made over. Whereas, although no woman can change herself from fair to dark or the reverse at will, it is quite within her power to manage the matter of color generally in her toilet so that the best possibilities she possesses in that line may be made becomingly conspicuous, where before they were simply swamped and passed for nothing. Color, in a word, is much more malleable than contour. It is more fluctuating and can more easily be controlled by a master hand. The popular fallacy that the best hues of the complexion, of the eyes, of the hair, are brought out alone by the color of the gown chosen, is indicative of very superficial observation. This is much, certainly, but it is not all. One item—the arrangement of the hair itself—has the greatest possible influence in emphasizing or toning hues in the skin or eyes. A blonde of the pink and-white variety might, if she were so minded, wear her hair very plainly in lines very simple and distinct and guiltless of frivolously escaping wind-blown curls and stray locks. The extreme purity of the milk-and-rose skin of a flaxen-haired blonde is brought out in its perfection by these straight yellow lines. On the other hand, should a sallow blonde do her hair in this way, the yellowish tints of the skin, unsoftened by that vaporous surrounding of gold which makes the complexion whiter by contrast, would stand out in uncompromising distinctness. Such a blonde should endeavor by frequent shampoos to keep her hair as fluffy and golden as possible. (A moderate dash of washing soda in the water tends to this end; and tar soap used regularly at short intervals will impart, after a certain length of time, an added bronziness to red-gold locks.) She should then arrange her hair with as close a reference to cloud-like effects as other considerations admit of. On the other hand, she should keep the markings of eyelashes and eyebrows as definite as possible, weeding out and pinching and brushing the latter into a clear arch. A sallow blonde should seek to have her entire color-effect as soft as possible and as light as airy. A fresh looking mouth is a great advantage to her—a mouth with very white teeth and very healthy pink lips and gums. She needs, and should by assiduous care cultivate these attractions, as they counteract the muddiness that her complexion may suggest if not relieved by just such side touches. A sallow, dark woman, on the contrary, should proceed, as to the arrangement of her hair, on principles directly different. Fluffy hair only increases the look of thickness, of yellowness in the skin. In any case, where the hair is black, a frowsy coiffure can never be wholly recommended. When the skin is exceedingly white, with a brilliant color in the cheeks and lips, it is sometimes becoming, but the instances are too rare to form a rule. With the olive complexion and all its derivatives, the whitest, the finest, and also the richest and softest hues of the skin are brought out by a mode of coiffure which allows the raven glossiness of the hair to show in its full measure and relief. This is possible only where the lines of the coiffure are either straight or waved in perfectly distinct curves. The markings of the hair about the face must be definite; not sharp, but clear. Slightly heavy eyebrows, provided they be quite smooth and not disfigured by stray hairs straggling out of line, are not a drawback. Very white teeth are an immense relief from the prevailing sallowness. Distinctness, then, and that peculiar cleanliness of outline and expression which this distinctness brings, are the elements a sallow, dark woman most should seek to bring out in her features by the management of her coiffure, etc. The item of showing much or little of the neck habitually, is another very determining factor in bringing out the most or least becoming tints in the skin. Where the features are rather massive and the general look of the complexion dull, the white reflection thrown by the greater fairness of the exposed throat is usually an improvement to both—usually, but not invariably. There are women of a softly, duskily Oriental coloring, around whose eyes are rich bistrous tints—Rembrandt like shadows in brown—who never look more lovely than with a high-throated collar or band of dark velvet

choked about their necks. These lines must be studied individually. As to the colors to be worn in costume, one large law holds good throughout. Choose carefully only those tints of which a duplicate may be found in some degree of approximation in the hair, the eyes, or the complexion. This is an artist's law and it is infallibly safe to follow. Whenever you get away from it you are in dire peril of shipwreck somewhere. Simple as it is, though, and easily ascertained and acted upon, how few are its votaries is glaringly apparent in every assemblage of women the world over. It is easy enough to match the eyes and hair, certainly, even if a woman have not a sufficiently delicate eye for color to enable her to decompose into its component semi-tones the general tinting of her skin. A woman with blue-gray eyes is always becomingly dressed in any of those indefinite blue shades in which much gray is mixed. Almost always, as it happens, eyes of that color are found in conjunction with a thin, neutrally tinted complexion, of the sort sensitive to atmospheric changes. Now, complexions of this order have a tendency to a certain delicate blueness about the eyes and occasionally about the mouth. Blue is then very visibly present in the skin as well, and forms another indication of the colors most likely to be becoming above all others. To a rather sallow woman, with bronze-brown hair and brown eyes, all shades of brown and of yellow are becoming beyond any other colors. There is yellow in her skin and a strong dash of yellow also in her hazel eyes, although she is probably quite unaware of the fact. Take a dazzlingly fair blonde, put her in pale green, and she is delicious. And why? Because, as any artist would tell you, there is in the mother-of-pearl whiteness of that porcelain-like skin a, to him, perfectly distinct admixture of the lightest, faintest, most ethereal green. But the green will be more becoming if she have blue eyes than if she have brown; and the reason is simple, since blue and green blend one into the other in the spectroscope—are sister colors. A brunette with the ivory-white skin that the French call "mat," is never so exquisite as in cream color, and obviously because, as nearly as can be achieved, she has reproduced the tinting of her skin in her gown. Put a colorless blonde in the same cream color, and she will look very far from charming, but exchange it for a pale gray, and lo! the difference. And again the reason is obvious. In the blonde's sallowness there are tints of gray, capable, in unhealthy skins, of becoming earthy. In the dark woman's pallor there are yellowish tones always, and these are prominent likewise in her cream-tinted gown. In choosing colors which have no match in eyes, hair or complexion, the guide is, once more, to select those tints one of whose components is present, at least, in some shape in the coloring given you by nature. Take red. A dark woman with a yellowish pale complexion chooses a red inclining either to purplish magenta or to rose—a red in which there is very little admixture of yellow—and her face looms up above it, yellow itself as a saffron bag. Had she chosen one of the bright reds of the shade known as Tuskish red, more or less, the yellow in that would have assimilated and sucked up, as it were, the sallowness of her skin, and made it look white by contrast. In certain delicate shades of dove-gray a trained eye detects a flush of pink, and the reason why such gray, worn by a woman, blonde or dark, but with a transparently rosy skirt, should be so entrancingly becoming, is not hard to find. To iron-gray hairs, and the more leaden hues of complexion which come with the passing of youth and maturity, what are more invariably becoming than white and black and their composite gray? It is not alone the soberness of these hues that then recommend them. The principal cause lies further back, in an unconscious perception of the fundamental harmony between the tints of nature in this case and the tints suggested by custom and common sense. Rosy blondes and women who have rather florid complexions look well in various shades of purple and lavender, because the red in both absorbs the flush in the skin and whitens its effect. A sallow skin in juxtaposition to these colors looks simply muddy, on the other hand, as there is nothing in its blended tints to correspond with the components of the hues themselves. In short, no garment of any sort, not even an accessory to the toilet, should be chosen without reference to this underlying principle of harmony in color if a woman wish to make the best of herself. Attentive observance of the idea soon develops a subtle power of distinguishing the various components of a color in the best trained eye. The marvel is only, in view of the enormous advantage thus gained for controlling results, that the faculty should have been suffered, in the large majority of instances, to remain so dormant, so undeveloped.

DOMESTIC DIETETICS.

SPECIALLY PREPARED, FROM PRACTICAL TESTS, FOR THE LADY READERS OF THE "AMERICAN ANALYST."

SEASONABLE FOOD.

June.

MEAT.—Beef, lamb, mutton, ham, kidneys, liver, sausage, veal.

GAME AND POULTRY.—Pigeon, chicken, duck.

FISH.—Anchovy, bass, bluefish, blackfish, cod, eels, clams, flounder, haddock, halibut, herring, lobsters, mackerel, mussels, perch, porgie, prawn, salmon, shad, turtle, trout, sturgeon, whiting, weak-fish.

VEGETABLES. — Beans, cucumbers, carrots, cauliflower, lettuce, onions, parsley, parsnips, potatoes, shallots, spinach, turnips, radish, rhubarb.

FRUITS. — Cherries, strawberries, bananas, pineapples.

PRACTICAL RECIPES.

CHESTNUT SOUP.—Shell a pound of chestnuts and boil them until the skins come off readily, then cover them with clear soup and let them boil until they are mealy; mash through a sieve and put the purée back on the fire; add two quarts of water and let it simmer for nearly half an hour, stirring frequently; skin, add a good lump of butter, season and serve.

SCALLOPED SWEET POTATOES.—Pare and slice some raw sweet potatoes. Butter a pudding dish, put in a layer of potato, sprinkle with bits of butter and granulated sugar; put in another layer of potato, then sugar and butter as before until the dish is filled. Over all pour enough cream or very rich milk to cover the potato. Set the dish in a pan of water, and let it cook on top of the stove until the potato is soft, then brown in the oven; grated nutmeg may be also used if liked.

BROILED SWEET POTATOES.—Raw and boiled potatoes are served in this manner. Cut the raw potatoes in thin slices, brush melted butter over them and also over the wire broiler to prevent their sticking to it; broil them a dark brown; boiled sweet potatoes need to be but slightly broiled, just enough to warm through and at the same time to show the marks of the broiler.

CODFISH CROQUETTES.—Pick a pound of salt codfish to pieces and let it soak for several hours in cold water, overnight if the croquettes are for breakfast. In the morning dry it and add to it the following cream sauce: Put two large tablespoonfuls of butter and three of flour in a saucepan and cook together; add a cupful of hot milk gradually, and rub smooth; add the beaten yolks of two eggs and the codfish, season with salt and pepper, cook for a few moments and pour into a dish to cool. Make into croquettes and fry in boiling lard.

CAULIFLOWER, TOMATO SAUCE.—Trim a head of cauliflower neatly and let it stand in salted water head downward, three-quarters of an hour; then put it in slightly salted fast boiling water and boiled just enough to be cooked, but not mushy when pressed between the finger. Test it with a long needle. After twelve minutes' boiling remove the scum that arises or it will discolor the cauliflower. Let it drain a moment. Put in the centre of a dish a liberal quantity of well-made hot tomato sauce; add the cauliflower and serve.

PRINCESS POTATOES.—Peel and boil four potatoes and let them get as dry as possible. Mash them through a sieve, and to a pound of potato put one and a half yolks of egg, one and a half large spoonfuls of butter, two large spoonfuls of Parmesan cheese, salt and cayenne pepper. Mix all together while hot. Let the mixture cool; then form into little rolls, using a very little flour to prevent sticking. Put the rolls, which should be about two inches long and one across, on buttered tins and bake them a nice brown. Dish up, pour melted butter and chopped parsley over them and serve.

CHOPPED HAM SANDWICHES.—Take a cupful of finely chopped cold boiled ham, the yolks of six hard-boiled eggs and a teaspoonful of French mustard. Mix the mustard well into the eggs, add the ham, and spread it between layers of thin buttered bread.

ELECTRICAL QUACKERY.

A CAUTION AGAINST A POPULAR HUMBUG.

Electricity is a word to conjure with. There is a something mysterious and awesome about its manifestations that excites the imagination of the untaught multitude, and prepares it to accept anything as possible when this protean agent is called upon to stand sponsor for it. It is, therefore, the most natural thing in the world that the electric field should be the very stronghold of quackery. It is most unfortunate that this should be the case, for, legitimately employed, electricity is at once one of the most powerful as well as beneficent curative agents known to the physician and surgeon. In several classes of physical ailments, notably in those affecting the nervous system, and in rheumatic affections, at once the most obscure in their origin and the most difficult to cure, it is almost unanimously agreed that the application of mild electric currents of an interrupted character affords relief, and frequently brings about a permanent cure where medication has signally failed. The forms of apparatus devised for the application of the electric current have been greatly improved and brought to a condition of high efficiency, and only the prevailing ignorance of the first principles of electric science, and the pernicious habit among a large class of the people of self-dosing and self-doctoring, are responsible for the electrical quackery that flourishes in our midst in the full tide of prosperity. In this classification belong the innumerable (so-called) electrical appliances for wearing upon the body—electrical pads for various organs, magnetic belts and chains, electro-magnetic shoes, and the like, to say nothing of electric combs and brushes, all and singular, claimed to possess the power of reviving the vital forces and rejuvenating the wearer. To those who may be disposed to lend a willing ear to the marvelous claims made for these paraphernalia of quackery, or to be deluded by the pictures of male and female persons bedecked with appliances from which electric sparks are being emitted with dazzling effect, we would give the advice of *Punch*—Don't! They are the veriest humbugs and absolutely worthless for their pretended purposes. We are fully prepared to admit that instances may be cited where some apparent benefit has been derived from these things, but such cases can be explained most rationally to be due to the influence of the imagination, and the same result would have been reached by other and equally worthless

agencies, such as the wearing of amulets, talismans, and the like, which is extensively practiced among the ignorant and credulous. The safe course to all who know nothing about electricity and its laws and manifestations, and who may be tempted by the glowing accounts issued in behalf of such trumpery humbugs as those above enumerated, is to ask medical advice before yielding to temptation.—*Manuf. and Builder.*

SOFT SOAP AND HARD.

ELOQUENCE OF A BOWERY FAKIR BEFORE AN EAST SIDE AUDIENCE.

A street fakir of the finest type stood at the corner of the Bowery and a cross street, New York, and addressed the attentive throng with all the rhetorical flourish of a United States Senator. "I was once a poor boy," said he, "with only two cents in my pocket, and I found myself here in this great city without a home and without a friend. May the fates preserve you from any such hardships as I saw, dear gentlemen! Barefooted, hungry, sleeping on the cold ground under the unsympathetic stars, eating the crumbs thrown to me from the tables of the rich, I was indeed a blighted being. I did my best to get employment, but there was no room for me, and I began to contemplate suicide. That was cowardly of me, gentlemen, I will admit, but I had been made a coward by my privations. I was not myself, and my suicidal purpose was the mad despair of a half insane youth. Yes, I was determined to commit suicide, and was starting in search of a secluded dock, where I could plunge into the cruel river without the danger of being rescued, when a piece of good fortune befell me which changed the whole course of life. As I was passing along the Bowery my attention was attracted by the voice of a gentleman who stood on a corner just above where I am standing now. He had a small black bag with him, very similar to the one I am carrying, and in this bag were small cakes of soap, which the gentleman was offering for sale at twenty-five cents a cake. Now, I did not much stand in need of soap at just that moment, notwithstanding the very thorough bath I was about to give myself, and I should not have stopped to listen to that gentleman had I not perceived that he was offering a very remarkable inducement to the public to buy his wares. Will you believe it, gentlemen, in many of the packages of soap contained in that bag were wrapped greenbacks ranging from the one to the five-dollar denomination! I was seized with an immense longing to try my luck in that soap lottery. Providence was watching me at that moment. The soap vender looked down and saw my sad face and tattered garments. 'There is a lad,' said he, 'whom I should like to help. He shall be permitted to draw a cake of soap from this bag without charge, and we shall see what his fortune will be.' I drew, gentlemen, as I was directed, and, joy of joys! there was a five-dollar bill in my cake of soap. A year later I had $1,000 in the bank, and now I am proud to say life is a perpetual delight. So much do I feel my indebtedness towards the gentleman who saved me that I, too, have taken up the philanthropic work of distributing bank bills among the needy, and I always make it a practice to precede my sales by allowing some poor, ragged boy in my audience to draw a cake of soap from the bag free of charge. Ah! there is a most unhappy face. My boy, select a cake from the bag; it will cost you nothing." The poor, miserable lad thus importuned did as he was directed, and as the crowd watched him unfold the paper wrapper it was seen that a five-dollar bill was inside. "You see," exclaimed the fakir, unwrapping several of the cakes to display the money within, and then throwing them back into the bag, "you can scarcely help drawing a prize." Instantly there was a rush in the soap business. As fast as the fakir could make change coins fluttered into his hands. The excitement continued for a number of minutes and then some one in the crowd began to complain that no prizes were turning up. It was then that the fakir discovered a policeman approaching, and hastily shutting his bag he hurried down the cross street, and turning sharply to the right after going a short distance, disappeared into a liquor saloon. He ordered whiskey for himself, and in a few minutes he was joined by the ragged boy who had been allowed to draw the five-dollar prize. His profits on the soap must have been fully $10.—*Soap and Perfumery Journal.*

THE STARFISH.

FIVE INDIVIDUALS IN ONE, WITH MANY LIVES.

"The attack of a starfish upon an oyster may be likened to an assault by organized conspirators, inasmuch as each of these five-fingered animals is composed of five distinct individuals," said a scientist to a writer, and he added: "Each of the starfish's five arms has its own mind, nervous system and thoughts, such as they are, and all five nerve systems simply meet in the centre where the arms are joined. Thus it may be said that the mental guidance of this complex creature and the management of its affairs are intrusted to a board of five members, who have communication with each other, but act without the intermediation of a presiding officer. Now, is it not wonderful that such a quintet should be able to manage its affairs so well and with such agreement of purpose in everything? Supposing that each of the five individuals attempted to go where it listed, without giving any heed to the others, the animal could not reach a choice bit of food, espied from afar with the eye of one of its members, nor travel in any direction with a purpose in view. But, as a matter of fact proved by observation, when a starfish is spying after its food it lifts the ends of its five arms so that the eye beneath each extremity may get a view of things in the neighborhood, and if any object worth going after is discovered, all the many hundreds of

Buffalo Lithia Water, Spring No. 2, in Bright's Disease, Gout, Stone in the Bladder, and Diseases Generally of Uric Acid Diathesis, Etc., Etc.

DR. WM. A. HAMMOND, of Washington, D. C., Surgeon General U. S. Army (retired), Professor of Diseases of the Mind and Nervous System in the University of New York, etc.

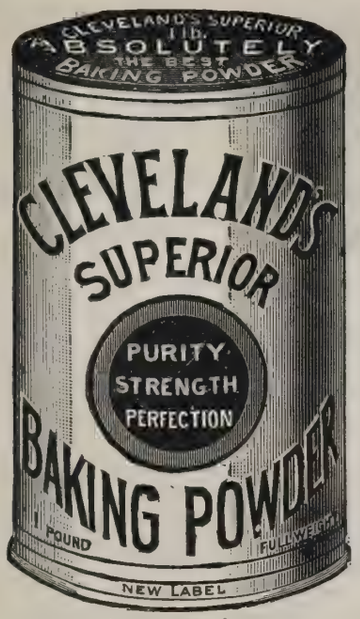
"I have for some time made use of the BUFFALO LITHIA WATER in cases of AFFECTIONS of the NERVOUS SYSTEM, complicated with BRIGHT'S DISEASE OF THE KIDNEYS or with a GOUTY DIATHESIS. *The results have been eminently satisfactory.* Lithia has for many years *been a favorite with me in like cases, but the* BUFFALO WATER CERTAINLY ACTS BETTER THAN ANY EXTEMPORANEOUS SOLUTION of THE LITHIA SALTS, and is, moreover, better borne by the stomach. I also often prescribe it in those cases of CEREBRAL HYPERÆMIA resulting from OVER MENTAL WORK—in which the condition called NERVOUS DYSPEPSIA exists—*and generally with* MARKED BENEFIT."

DR. WM. B. TOWLES, Professor of Anatomy and Materia Medica, in the Medical Department of the University of Virginia.

"BUFFALO LITHIA SPRINGS, No. 2, belongs to the ALKALINE or, *perhaps, to the* ALKALINE SALINE Class, *for it has proved far more efficacious in many diseased conditions than any of the simple* ALKALINE waters.

"*I feel no hesitancy whatever in saying that in* GOUT, RHEUMATIC GOUT, RHEUMATISM, STONE *in the* BLADDER, and in all diseases of URIC ACID DIATHESIS, *I know of no remedy at all comparable to it.*

"*Its effects are marked in causing a disappearance of* ALBUMEN *from the urine. In a* single case of BRIGHT'S DISEASE *of the* KIDNEYS, I witnessed *decided beneficial results from its use, and from its action in this case I should have great confidence in it as a remedy in certain stages of this disease.* In DYSPEPSIA, especially that form of it in which there *is an excessive production of* ACID *during the process of nutrition*, in some of the PECULIAR AFFECTIONS *of* WOMEN, notably in SUPPRESSION of the MENSES, and in CHRONIC MALARIAL POISONING, etc., I have found it highly efficacious."



DR. G. HALSTEAD BOYLAND, late Professor of Surgery, Baltimore Medical College, late Surgeon French Army (Decorated), Member Baltimore Academy of Medicine, Member of American Medical Association.

"In BRIGHT'S DISEASE of the KIDNEYS, ACUTE or CHRONIC, BUFFALO LITHIA WATER, Spring No. 2, is, in my experience, *without a rival*, whether in the PARENCHYMATOUS form or INTERSTITIAL NEPHRITIS. In cases in which the ALBUMEN in the URINE reached as high as 50 per cent., I have known it under a course of this water gradually diminish and finally disappear, at the same time other alarming symptoms were relieved and the sufferers restored to health.

"In STONE in the BLADDER of the RED LITHIC ACID and the WHITE PHOSPHATIC DEPOSIT, the SOLVENT power of this water is *unmistakable.*"

Water in cases of one dozen half gallon bottles, $5.00 f. o. b. here.

THOS. F. GOODE, Proprietor, BUFFALO LITHIA SPRINGS, VA.

The Key to Success

in washing and cleaning is *Pearline*. By doing away with the rubbing, it opens the way to easy work; with *Pearline*, a weekly wash can be done by a weakly woman. It shuts out possible harm and danger; all things washed with *Pearline* last longer than if washed with soap. Everything is done better with it. These form but a small part of the—Why women use millions upon millions of packages of *Pearline* every year. Let *Pearline* do its best and there is no fear of "dirt doing its worst."

Turn the Key

On the peddlers and grocers who tell you "this is as good as," or "the same as" Pearline. IT'S FALSE; besides, Pearline is never peddled

236 JAMES PYLE, New York.

sucker-like feet beneath the five arms are seen to push out together in the direction of the morsel desired. There is a unity of intention among the partners that implies unmistakably a conscious sharing of aim and design. The same thing is shown by the way many starfish have of letting themselves drop from steep rocks and cliffs, in order to save the trouble of laborious climbing down. In such cases, before they relinquish their hold and drop, they let go with three or four arms, holding fast until the last moment with the remaining one or two, as if it were to calculate the leap. My observations on this subject have inclined me to think that matters of concerted action with starfish have not infrequently to be effected by first obtaining the assent of an individual ray that is willing. It is known that these creatures sometimes divide themselves voluntarily into a three-armed and a two-armed portion, which may be regarded as the violent dissolution of business, and domestic relations once happy but grown inharmonious. A starfish will often cast off one of its arms and leave it behind, perhaps because the member is not found agreeable to live with. If a rubber band or a string is fastened around an arm of one of these animals, and it cannot push the annoyance off with its other arms, the starfish will throw the troublesome arm away, not desiring to retain the companionship of such a cripple. Starfish are like human beings in many ways. Then the animal which has thus deprived itself of a ray grows a new one in place of the old. As for the arm that is dropped, it promptly proceeds to grow four new arms, thus becoming a whole starfish itself. Being the biggest, it is presumably for a long time the boss of the five, which must be gratifying. A few years ago people who caught starfish in the oyster beds destroyed them, as they thought, by cutting them in halves and throwing them overboard, but the process was not very effective, inasmuch as every one thus treated promptly became two."

MICROSCOPIC LENSES.—It is stated that an immense improvement has recently been effected in the manufacture of glass for optical instruments by means of the addition to the ordinary materials of phosphorus and chlorine, which in some as yet unexplained way cause the glass to be very much more transparent, and enable it to receive a much higher degree of polish than any optical glass hitherto manufactured. Thus microscopes can be made which will render objects of the diameter of only the one eight-millionth of a millimeter visible, whereas with the best instruments now in use the diameter of the smallest object that can be seen is one sixteen-thousandth of a millimeter. This news, we fear, is too good to be true.

ADULTERATIONS IN ROME.—The Roman authorities propose to cure the commercial vice of adulteration by the publication in the daily papers of the names of all makers and venders of food substances which are adulterated or injurious to health.

CALIFORNIA TIN.—The first ingots of tin ever made in California lately arrived in San Francisco from the mines of the San Jacinto estate, Cajalco, San Bernardino County. These are what were known as the Temescal tin mines, which were discovered many years ago. Litigation and other causes have prevented the claims from being developed, but now an English company has purchased and equipped them for actual work. Oil fuel is used in the furnace, this being much cheaper in that region than coal. The experiments with the reverbatory furnace and oil fuel seem to be successful.

WATCH GLASSES.—It is interesting to know something of the details and labor connected with the production of these handy adjuncts to the laboratory. The glass is blown into a sphere about a meter in diameter, sufficient metal being taken to give the required thickness, as the case may be. Disks are then cut from this sphere with the aid of a pair of compasses having a diamond at the extremity of one leg. There is a knack in detaching the disk after it has been cut. A good workman will cut 6,000 glasses in a day.

POISONOUS DRY GOODS.—The British consul at Christiania, in Norway, about four months ago forwarded a letter calling the attention of the Foreign Office to the fact that, owing to the English printed fabrics containing arsenic, there had been a great decline in the quantity of such goods imported into Norway, and the British printed cloths were getting a bad reputation in consequence of their containing such a large excess of arsenic. This letter was forwarded to the Manchester Chamber of Commerce, which procured samples of the goods in question, and they were handed over to Mr. Ivan Levinstein, who had the samples examined, and they were found to contain arsenic in large quantities.

PHONOGRAPHY AND STENOGRAPHY.—The phonograph, it seems, is destined to seal the fate of the stenographer, said an author of note yesterday: "A few weeks ago I used to hurry down town to keep an engagement with my stenographer and he in turn to meet the typewriter later. Now I take my leisure in the morning, and while dressing talk for a half hour or more into my phonograph, box up the cylinder and send it to a typewriter. She takes down everything that the cylinder says, and before noon the same day I receive a neat typewritten copy of my earliest thoughts. If anything strikes my mind forcibly during the night, or if I am troubled with insomnia, I place the phonograph by my bedside and start the cylinder revolving. Is it expensive? Why, bless my soul, no! not a tenth of what it would be were I to engage a stenographer. It costs me $40 a year for the rent of my phonograph and about $2 a dozen for my cylinders. Not very high for the ease and comfort it affords, is it?"

BICYCLES

GIVEN AWAY TO BOYS AND GIRLS!

AN OPPORTUNITY OPEN TO ALL.

The Analyst Publishing Company being desirous of largely increasing their subscription list, will furnish every one with a beautiful Safety Bicycle, ABSOLUTELY FREE, in return for a few hours' canvassing.

To every boy and girl who secures 75 subscribers for the American Analyst at $75, we will give a splendid

$40.00

NONPAREIL

SAFETY BICYCLE.

These bicycles are adapted in size to boys, but are strong enough to carry a man. A boy's bicycle should be a strong one. They are manufactured by the Overman Wheel Co., the makers of the celebrated Victor Bicycle, and have the full guarantee of the makers.

The following is a brief description of the NONPAREIL SAFETY; 26-inch wheels; ball bearing all around, including pedals; solid crescent rims; double tangent spokes; three-fourths inch tires; cranks, three throw, $4\frac{1}{4}$ to $5\frac{3}{8}$ inches; guards to both wheels; tool-bag, oiler and wrench. Finished in bright enamel, all exposed metal heavy nickel-plate on copper.

In selecting these machines as a premium, we have disregarded cheapness and selected a Bicycle which is serviceable, and the makers of which have an established reputation for building the best Bicycle that money, machinery and brains can produce. We are actually furnishing the Bicycles and Papers at less than cost, but hope by stimulating active and successful canvassing, and thus enlarging our subscription lists, to make an eventual profit. We positively guarantee these bicycles to be just as here represented. They will be shipped by express f. o. b. in New York.

Subscription orders must be made out plainly and legibly, and sent as fast as secured, addressed to

THE ANALYST PUBLISHING CO., 19 Park Place, New York.

WATCHES.

EVERY one wants a watch, and naturally a good watch that keeps accurate time, presents a handsome appearance, and is inexpensive. If such a watch can be found of American manufacture, it is an additional appeal to our patriotism. Just such a watch as this ideal The Analyst Publishing Company is enabled to offer as a Premium to its readers. Having some large advertising contracts we have been enabled to procure the movements of the manufacture of the best known American watch factories, namely, the Waltham, Elgin, Hampden and Illinois Watch Companies. These movements are adapted for both ladies' and gentlemen's watches, and are warranted by the makers. These movements have seven jewels, patent lever movement, chronometer balance, patent safety pinion, sunk hard-enameled dial, straight line visible palette, stem winders, hand set; in fact, contain all the latest improvements and can be readily cleaned or repaired by any ordinary good watchmaker. They can be regulated to run as close as any movement.

It is needless to say that to case these movements in solid gold cases would make them too expensive, yet they are cased in what are known as gold filled or stiffened "Ladd" cases, and are warranted to be 14 karat gold, made from two sheets of 14 karat gold overlaying fine composition metal, with regular jointed caps, covers and bezels, and to wear at least five years. They are not plated, nor rolled gold, but actual 14 karat gold cases, thin of course, but stiffened and strengthened by being filled with this fine composition metal. They are finished in the same manner, engine turned and engraved as solid gold watches, and wear and look just the same. No one but an expert can tell them from a solid gold watch. These watches are made both open face and hunting case style, in gentlemen's or ladies' sizes. For gentlemen we recommend plain engine-turned cases; for ladies, a handsomely engraved case.

How to Obtain One of these Watches.

These watches are not to be purchased from us at any price. Send us a club of 25 subscribers to the American Analyst, and $25, the regular subscription price, and one of these watches (your choice of style and size) will be immediately forwarded, post-paid and registered, to your address. You need not wait until you have your 25 subscribers all together, but forward them as you get them and they will be credited to you, and when the number is complete the watch will be sent. A subscription for two or three years will be counted as two or three subscribers.

As these watches are retailed by jewelers at not less than $25, it will be seen that we are offering a real premium with the sole object of increasing our circulation, and that by taking advantage of our offer any one can obtain a good, reliable and handsome watch without cost. As the number of these watches at this price is limited, it is advisable to take steps at once to procure a bargain.

BOSTON HAY AND STRAW MARKET.

Hay, choice to fancy, in large bales.	$15.50 to	$16.50
Hay, choice to fancy, perpetual pressed bales	14.50 to	15.50
Hay, fair to good	14.00 to	15.00
Hay, poor to ordinary	12.00 to	13.00
Hay, Clover and Clover mixed	11.00 to	12.50
Hay, swale	8.50 to	9.00
Straw, Rye, good to prime	16.50 to	17.50
Straw, Oat	8.00 to	

BOSTON, June 20, 1891.

Receipts for the week are 292 cars of Hay and 45 cars of Straw; corresponding week last year, 282 cars of Hay and 48 cars of Straw. Receipts of hay are fairly liberal, but the market is firm for all grades; some choice cars selling above our quotations. As is usual on a strong market, hay is not graded as close, and the medium grades sell nearer up to the price of the best than would be possible on a dull market.

Receipts of Rye straw are in excess of demand and market is dull and easier.

Subscription $1.00 per year. Now is the time to subscribe.

Tabasco Pepper Sauce

OR LIQUID PEPPER.

Is simply the Pulp of the Ripe Pepper Extracted by Pressure.

The seed of this Pepper was obtained from Central America, and by careful cultivation in Louisiana for many years has been so improved in strength, flavor and aroma, as to have become a new variety of Red Pepper, superior to all others. The pulp is so handled as to retain all the flavor, strength, aroma and color of the ripe fruit, and to keep unimpaired in any climate. It excites the appetite, promotes digestion, and is pronounced, by connoisseurs, to be the finest condiment in the world. For medicinal purposes it recommends itself by its purity, strength and diffusible form.

INSTRUCTIONS TO SUBSCRIBERS.

The **Names of all Subscribers** are registered as soon as received, and paper is always promptly forwarded.

Postage.—The postage to all parts of the United States and Canada is paid by the publisher.

Remittances of small sums may be made with comparative safety in ordinary letters. Sums of one dollar or more must be sent by registered letter or P. O. money order, otherwise we cannot be responsible for same. Silver must not be sent in a letter.

Postage Stamps will be received for the fractional part of a dollar, and in any amount when it is impossible for patrons to procure bills, but you must send one or two-cent stamps only.

SUBSCRIPTIONS.—The AMERICAN ANALYST will be sent one year to any subscriber for ONE DOLLAR. New subscriptions can begin at any time.

We Stop the Paper at the expiration of the time paid for unless a renewal of subscription is received. Those whose subscriptions have expired must not expect to continue to receive the paper unless they send the money to pay for it.

Change of Address.—Subscribers wishing their addresses changed must invariably give their former as well as new address.

Missing Numbers.—It occasionally happens that numbers of our paper sent to subscribers are lost or stolen in the mails. In case you do not receive any number when due, write us a postal card and we will cheerfully forward a duplicate of the missing number.

Most Important of All.—In every letter that you write us, never fail to give your full address, plainly written—name, post-office, County and State.

Address all letters to

THE ANALYST PUBLISHING CO.,
19 Park Place, New York.

GRAND PREMIUM OFFER!

A SET OF THE

WORKS OF CHARLES DICKENS,

In Twelve Large Volumes,

Which we Offer with a Year's Subscription to this Paper for a Trifle More than Our Regular Subscription Price.

CHARLES DICKENS.

Wishing to largely increase the circulation of this paper during the next six months, we have made arrangements with a New York publishing house whereby we are enabled to offer as a premium to our subscribers a **Set of the Works of Charles Dickens, in Twelve Large and Handsome Volumes,** with a year's subscription to this paper, for a trifle more than our regular subscription price. Our great offer to subscribers eclipses any ever heretofore made. Charles Dickens was the greatest novelist who ever lived. No author before or since his time has won the fame that he achieved, and his works are even more popular to-day than during his lifetime. They abound in wit, humor, pathos, masterly delineation of character, vivid descriptions of places and incidents, thrilling and skillfully wrought plots. Each book is intensely interesting. No home should be without a set of these great and remarkable works. Not to have read them is to be far behind the age in which we live. The set of Dickens' works which we offer as a premium to our subscribers is handsomely printed from entirely new plates, with new type. The twelve volumes contain the following world-famous works, each one of which is published *complete, unchanged, and absolutely unabridged:*

DAVID COPPERFIELD,
MARTIN CHUZZLEWIT,
NICHOLAS NICKELBY,
DOMBEY AND SON,
BLEAK HOUSE,
LITTLE DORRIT,
OUR MUTUAL FRIEND,
PICKWICK PAPERS,
BARNABY RUDGE AND CHRISTMAS STORIES,
OLIVER TWIST AND GREAT EXPECTATIONS,
THE OLD CURIOSITY SHOP AND THE UNCOMMERCIAL TRAVELER,
A TALE OF TWO CITIES, HARD TIMES AND THE MYSTERY OF EDWIN DROOD.

The above are without question the most famous novels that were ever written. For a quarter of a century they have been celebrated in every nook and corner of the civilized world. Yet there are thousands of homes in America not yet supplied with a set of Dickens, the usual high cost of the books preventing people in moderate circumstances from enjoying this luxury. But now, owing to the use of modern improved printing, folding and stitching machinery, the extremely low price of white paper, and the great competition in the book trade, we are enabled to offer to our subscribers and readers a set of Dickens' works at a price which all can afford to pay. Every home in the land may now be supplied with a set of the great author's works.

GLENN'S
SULPHUR SOAP.

Glenn's Sulphur Soap is the **Original** and **Best** combination of its kind, and the one now generally in use. For sale by **All Druggists.**

BEWARE OF COUNTERFEITS.

Be progressive and keep abreast of the times. Avoid dyspepsia by using **Lard Compound** and **Cottolene,** a substitute for lard.

The highest medical authorities pronounce them healthful; and expert cooks commend them.

Our **Clairette** brand of cotton oil soap is the purest and best laundry soap in the market; as pleasant to the hands as genuine castile.

N. K. FAIRBANK & CO.,
CHICAGO AND ST. LOUIS.

OUR GREAT OFFER
TO SUBSCRIBERS
TO THE
AMERICAN ANALYST.

We will send the **ENTIRE SET OF DICKENS' WORKS,** *in* **TWELVE VOLUMES,** *as here described, all postage prepaid by ourselves, also* **THE AMERICAN ANALYST** *for* **ONE YEAR,** *upon receipt of* **$1.50,** *which is only* **50** *cents more than the regular subscription price of this paper.* Our readers, therefore, practically get a set of Dickens' works in twelve volumes for only **50** cents. This is the grandest premium ever offered. Up to this time a set of Dickens' works has usually been $10.00 or more. Tell all your friends that they can get a set of Dickens' works in twelve volumes, with a year's subscription to **THE AMERICAN ANALYST** for only **$1.50.** Subscribe now and get this great premium. If your subscription has not yet expired, it will make no difference, for it will be extended one year from date of expiration. We will also give a set of Dickens', as above, free and post-paid, to any one sending us a club of three yearly subscribers.

MICROSCOPISTS IN SESSION.

The American Society of Microscopists, of which the genial Frank L. James of St. Louis is President, will hold its fourteenth annual meeting in Washington, D. C., August 10, and continue in session five days. Its roll of active members contains about three hundred and fifty names, embracing very nearly every person in the United States who is at all prominent as a microscopist. Its membership consists of two distinct classes, viz.: professional men and students of the natural sciences, who use the microscope in their daily avocations as an instrument of research, diagnosis, or precision; and amateurs, or those who find pleasure and profit in the revelations of the instrument. Many of the latter class, from having early chosen special lines of study and investigation, have acquired high reputations in their respective departments of microscopical research. In its earlier years this class predominated in the membership of the society, but at present the professional element is largely in excess. The qualifications for membership are very simple. The applicant must be a respectable person socially, and interested in the use of the microscope. The advantages of membership are dual in their nature, *i. e.*, general and social, or those which accrue to the individual from associations with others engaged or interested in the same pursuits in any and all walks of life; and special, in that the meetings of the society are to a certain extent educational in their nature. In the "Working Sessions" experts in every department of microscopical technology are engaged in giving manual demonstrations of the details of their lines of work; in the informal evening "conversaziones," the room of every worker who has anything special to exhibit or demonstrate, is open for the reception of all those who wish to witness the demonstration; finally the soirée affords an opportunity of displaying for the benefit of the members, as well as the public generally, all that is most beautiful, interesting and instructive in the cabinets or laboratories of the exhibitors. Of late years the soirées have been attended by many thousands of visitors in every city in which the society has met, and have been regarded as distinguished social as well as scientific events.

DRIED BANANAS.

A new industry is reported to be gaining headway in the tropics. Drying bananas for shipment has been tested in Trinidad, West Indies, with marked success. A report received by the Bureau of American Republics sets forth that the cost of producing a bunch of bananas weighing fifty-two pounds, including the purchase of land, clearing, draining, planting, weeding, cutting, drying, fuel, boxes and packing for market would average only 53 cents. The fruit in drying loses one-third of its weight. When dried it sells readily at 16 cents a pound. Allowing for the loss of weight this would yield $2.72 a bunch—a clear profit for the grower of $2.19. An order for several hundred pounds of the dried fruit, at 12 cents a pound, for the London market has been received at Trinidad. An actual sale of nearly a hundred boxes of the dried fruit has recently been made in Canada at 20 cents a pound. Over one hundred thousand plants have been distributed in Trinidad and Tobago within the last two years. The purchasers were principally large planters, and there is every indication that the industry will be persued on an extensive scale and that dried bananas will soon be an important item in the commerce of the West Indies. The dried fruit can be conveyed to market from remote districts over bad roads without injury, and the risks of handling and of the sea voyage are reduced to a minimum. This is an entirely new and valuable industry. The banana is the most productive of all fruits. Once planted it perpetuates itself, and the trouble is often to get rid of it. Its productiveness is said to be 42 times greater than that of the potato and 131 times greater than wheat. The dried product is not only palatable as a fruit, but is a nutritious article of food. There is practically no limit to the amount that can be produced.

APPROPRIATING A NAME.

The desire to have things appear different from what they seem, often brings trouble and disgrace upon people who to further their present ends foolishly place themselves in false positions. If an individual supposed to be respectable uses the name of a prominent physician without authority, as is alleged in the item of news given below, what confidence can be put in any other statement he may make? The item may also be a lesson to others to teach them that honesty is the best policy.

Sir Morrell Mackenzie, the distinguished British physician, has, through Simon Sterne of this city, his counsel, brought suit for $10,000 damages against the Soden Mineral Springs Co. and the Eisner Mendelson Co., of No. 6 Barclay Street, for the unauthorized use of his name in connection with a proprietary medicine manufactured by them. As a preliminary step Mr. Sterne obtained yesterday from Judge Miles Beach in the Supreme Court a temporary injunction restraining defendants from using Sir Morell's name, and naming Tuesday next as the time for hearing argument why the injunction should not be made permanent. In his complaint Sir Morrell sets forth that such use of his name by defendants on their wrappers, circulars, and advertisements is injurious to his professional standing, and offensive to his feelings. It is, he says, a part of the written and unwritten code of medical ethics throughout the civilized world that a professional physician should have no interest in any proprietary medicine or surgical instrument, and that he shall not recommend patent medicines for indiscriminate use by the public, because no remedy can be safely recommended without knowledge of the special condition and circumstances of the patient, and the publication of such indiscriminate recommendation casts upon the physician the suspicion that he has a personal pecuniary interest in the medicine to the great and irremediable loss of his prestige and professional standing.

SUICIDAL ADVERTISING.

THE LITHIA WATER HUMBUG.—All the widely advertised American Lithia waters combined contain less lithia than many of Carl H. Schultz's mineral waters, which make no claim to be called lithia waters. His Kissingen, for instance, contains 173 times as much lithia as Buffalo.—*Advt.*

When advertisers are so far forgetful of business amenities, as to attack every other business man who may be more or less directly in competition with them, it arouses the suspicion of the public that they dare not depend upon the excellence of their own manufactures in offering them to the public, but strive to sell their goods by throwing mud at their neighbors. Mudslingers are almost always mendacious. Truth does not make a good missile for them and such people have no use for it. We are led to these remarks by an

advertisement of Carl H. Schultz, a manufacturer of alleged mineral waters which the public is asked to believe are made artificially in exact imitation of the natural waters. Seeing that Mr. Schultz's advertisement contains the most remarkable statement that his "Kissingen for instance contains 173 times as much lithia as Buffalo," we forbear from further comment. It may be possible that Mr. Schultz, if brought to proof could easily show that as his Kissingen contained no Buffalo whatever he could readily put 173 or any other number of times more lithia. In any case no one will believe his preposterous statements and therefore his advertisement is a boomerang and suicidal.

MINERAL WATER FRAUDS.

In Paris recently it was discovered that a party was offering some of the mineral waters below the usual prices. They purported to be the natural waters of Vichy, Vals, St. Jean, and other natural springs. The suspicion that something was wrong led to an investigation, and an establishment was found in which a large business was being done in making these waters artificially and counterfeiting all the external appearances in the way of labels, stamping the corks, capsules, etc. The proprietor, M. Monplat, was tried and convicted, and is now enjoying a rest of six months (in prison), and has been depleted in his purse to the extent of a fine of $600 and damages of $1,000, and his assistant to a fine of $20 and imprisonment for fifteen days.—*Pharmaceutical Record.*

We do not need to go to Paris to find fraudulent mineral waters. New York is full of them. There is hardly an artificial mineral water made that even bears a similarity to the natural water it is claimed to be an imitation of. The truth is that very few of the so-called natural mineral waters are what they claim to be. Additions of salts and charging with carbonic acid gas are among the least reprehensible sophistications.

STALE BREAD.

HOW A SHREWD BAKER ESTABLISHED A BIG TRADE.

The following story of the success of a New York baker and his disposal of stale bread is told by the *Herald:* "It has been a question for many years what becomes of the many billions of pins that are made in all parts of the world, and a similar query might be made concerning loaves of bread which have become too stale for use by the ordinary consumer. When bread which has been bought and not eaten confronts the housewife she knows of various uses for it. There are many uses for bread-crumbs in artistic cooking. The French cook can find, it is asserted, a thousand uses for stale bread crumbs. But stale bread in the shop is another thing. Large baking concerns who supply grocers with their product are now making a practice of taking back the unsold supplies of the day before. A few years ago a certain German-American started business with a borrowed barrel of flour. He had a well defined idea of how he intended to secure trade. This idea took the form of giving the grocer a guarantee that all unsold loaves would be taken back at their full wholesale price. This plan worked admirably, for many grocers who had not heretofore handled bread saw an opportunity for a possible profit and no loss. What the baker's original idea for the disposition of his stale loaves was is not very clear, but it did not appear to be the kneading over of the old into new material, as a great many people suppose bakers are in the habit of doing. Under the new order of things grocers began to make inroads into the trade of the small bakers, and the man who started with his owed-for barrel soon extended his business until it occupied a building half a block in length. As there is scarcely a product in the world to-day of which the waste cannot be turned to some profitable use, so it was with the baker's stale loaves. Many of the poor people of the neighborhood got their bread at a reduced rate because it was one day old, but the problem of disposing of the whole stock each day was finally solved by the Italians. One by one they dropped into the bread factory for stale loaves, until finally there was a regular colony of dealers, male and female, who took all they could get at a price which paid the maker for his extra handling, yet much lower than the price given grocers. The large Italian settlements in Williamsburgh and Brooklyn are fully covered by certain of the dealers. Others of them cover the Harlem district. The chief camping-ground of the stale bread vendors, however, is Mulberry Street and its intersections. This is the quarter where the man with the bag of bread can always be sure of selling out. In fact, the supply never equals the demand."

FIRE CRACKERS.

WHENCE THEY COME AND WHITHER THEY GO.

The annual jubilee which the enthusiastic and small American patriot celebrates with the popping off of fire crackers is again at hand. Despite their association with the celebration of American Independence, fire crackers are essentially a Chinese institution, and their importation constitutes a significant item in the commerce between the two nations. The annual receipts of fire crackers in this country are from eight hundred thousand to one million boxes, and orders for these goods have to be sent forward one year in advance. The Chinese manufacturing year begins June 1, and this is about the date when American merchants send forward their order for next year's supply. The usual voyage from New York to Hong Kong is 120 days, so that there are only left, after a passage to China and return, 125 days of the year. Crackers are made principally in Canton and in the country surrounding that city. A cannon cracker factory in the suburbs of Canton is described by an eye witness as follows: The building is of sun-dried brick, with a tiled roof twelve feet from the ground, and this space is divided into an upper and lower apartment, each with the ceiling about six feet high. The interior of the building when visited was strewn with pieces of paper, while vessels containing powder were standing round, the contents of which seemed to be in imminent danger of being exploded, and men, women and children were actively engaged in the manufacture of the goods. The paper needed for the cracker is cut to the required length and then weighed to see that the quantity for each cracker is exactly the same. The instrument used in weighing is of the rudest description, being a stick about two and one-half feet long, suspended from the ceiling by a string, which is attached to the centre of the stick, and a stone is placed as a weight on one end and the articles to be weighed on the other. The paper is rolled into cylindrical form by means of a flat piece of wood held in the hands, and then one hand is creased with a pair of pincers and a string tied into the crease as a temporary means of preventing the powder from running out when the cylinders are placed in a perpendicular position to be loaded. The last named process is as follows: The cylinders are bunched together like cigars turned on end, and then pinched with an awl, and into the aperture thus made the powder is poured from a tin can. Then the stem of the cracker is inserted which consists of a piece of thin, touch paper, with just sufficient powder twisted up in it to make it burn quickly. A piece of paper is temporarily pasted over the end containing the stem for the purpose of preventing the powder from running out, as the crackers are now placed on that end. The string placed temporarily around the pinched end is now removed and clay tamping is hammered into the aperture and then the paper is removed from the stem end and the clay tamping is applied there, which prevents any powder from sifting out. The cracker is now ready for the thin piece of red paper which goes around the outside and completes it. The stems are then very neatly braided together, which forms the crackers into packs, and these are each wrapped in thin paper and ornamented with a red label with pictures of dragons upon it. Red is the festive color of China, and as fire crackers are used principally on festal occasions, that color is rigidly adhered to in the manufacture of these goods. The packs are placed in boxes and in the proportion of forty packs to the box. There is a regular division of labor in the cracker factory, each person having his or her special work to do, and in this they become very expert. The above is a description of cannon cracker manufacture, but the same will apply to the small crackers. The latter, however, are generally made in the rural districts, and are brought down the river to Canton in junks. There is a large home consumption of fire crackers, and the Chinese think that their explosion will ward off evil spirits. They are fired off on numerous occasions, but particularly on the Chinese new year, which is a variable date regulated by the changes in the moon. Foreigners residing in Canton have what they call the Canton salute, which consists in the firing off at one time of six boxes of small crackers and two or three boxes of cannon crackers, and this is given on the departure of some one of their number for home. Of the million boxes of crackers sent each year to this country, a number are reshipped to South America, where they are used on social occasions as well as at public fetes. They are used in the south at Christmas time, and also in Canada on May 24, which is Queen Victoria's birthday. Cannon crackers are made in this country, but the small ones cannot be produced here at anything like the price they can be furnished by the Chinese. Their product is carried half way round the world, pays duty, and is then sold for 85 cents a box. Fire crackers are of very ancient origin. Dr. Williams in his exhaustive work on China, entitled "The Middle Kingdom," says: "No evidence exists of the use of gunpowder as an an agent of warfare until the middle of the twelfth century, nor did a knowledge of its propulsive effects come to the Chinese until the reign of Yunglop in the fifteenth century—a thousand years after its first employment in fire crackers."

BRITISH WASTE PAPER.

WHAT BECOMES OF THE GOVERNMENT WASTE PAPER.

The waste paper branch of the business at her Majesty's stationer office is a very important one, says the London *Daily News.* It is situated in Earl Street, Westminster, a few minutes' walk from the main establishment. In the good old days waste paper went as the "perks" of Government officers. The more they sold the fatter they grew, and the sturdier, we may be sure, they stood up for the Queen and Constitution, and everything that was staid and respectable and conservative. The best of it was that it often happened that the very men who grew fat on waste paper had the ordering of the stock, and the more they ordered the greater were the "perks" of course. It was a delightful arrangement, but it was too good to be permanent, and in 1852 it was ordered that all waste and unserviceable papers, pens, old directories and other publications, and old and useless and worn out stores of every kind should be returned to the Stationery Office, and latterly, therefore, there has been one stream of new stationery from Westminster to all the Government offices in the kingdom, and a return current of used-up material. It pours in in huge van-loads to the establishment in Earl Street, where premises, formerly in the occupation of a marble mason, have been converted into a busy scene of industry in unpacking, sorting, cutting up, repacking and despatching to the paper mills, that may be witnessed all the year round. Till some years ago papermakers contracted for the waste paper here, and entered into a bond to destroy it forth-

with. This proved to be unsatisfactory, and there seemed to be no sufficient security against the leaking out of information that ought to be private and confidential. For some time public waste paper was sent to one or two of the prisons in London, to be torn up and sorted by the prisoners. This was not very successful either, and five years ago the Earl Street premises were taken, and everything now goes there. Vans run into the yard with their paper and books stuffed into gunny bags, which are hauled on up to a top floor and turned out upon tables, the tops of which consist mainly of iron gratings. Young women stand at these tables and sort out the paper into ten classes. Much of the stuff is very dusty, and the table tops are grated, so that as the paper is tossed about the dust may fall down below. Once a fortnight the screen round underneath the table is removed and the accumulated dust cleared out. The sorted papers are thrown into different hoppers, and are shot down to the floor below, where there is a tremendous guillotine cutting-machine, driven by a gas engine. All sorts of secrets and confidential communications are here chopped up so far as to render them unintelligible, and then they are packed up for dispatch to the mills, when purchasers come forward with satisfactory offers. Much of the waste is removed back into gunny bags, which are suspended from hooks in the ceiling, and may be rammed full with a sort of Herculean club which some of the damsels employ for the purpose ; but most of them apparently prefer to get into the bags and dance up to the top as their companions keep feeding in the waste.

ADULTERATION IN MASSACHUSETTS.

STATE LAWS FOR THE SUPPRESSION OF ADULTERATED FOOD AND DRUGS.

1. No persons shall, within this Commonwealth, manufacture for sale, offer for sale, or sell any drug or article of food which is adulterated within the meaning of this act.

2. The term "drug" as used in this act shall include all medicines for internal or external use, antiseptics, disinfectants and cosmetics. The term "food" as used herein shall include confectionery, condiments and all articles used for food or drink by man.

3. An article shall be deemed to be adulterated within the meaning of this act :

(*a.*) In the case of drugs—(1). If, when sold under or by a name recognized in the United States Pharmacopœia, it differs from the standard of strength, quality or purity laid down therein, unless the order calls for an article inferior to such standard, or unless such difference is made known or so appears to the purchaser at the time of such sale. (2.) If, when sold under or by a name not recognized in the United States Pharmacopœia, but which is found in some other pharmacopœia, or other standard work on *materia medica*, it differs materially from the standard of strength, quality or purity laid down in such work. (3.) If its strength or purity falls below the professed standard under which it is sold :

(*b.*) In the case of food—(1.) If any substance or substances have been mixed with it so as to reduce, or lower, or injuriously affect its quality or strength. (2.) If any inferior or cheaper substance or substances have been substituted wholly or in part for it. (3.) If any valuable constituent has been wholly or in part abstracted from it. (4.) If it is an imitation of, or is sold under the name of, another article. (5.) If it consists wholly or in part of a diseased or decomposed, putrid or rotten animal or vegetable substance, whether manufactured or not, or, in the case of milk, if it is the produce of a diseased animal. (6.) If it is colored, coated, polished or powdered, whereby damage is concealed, or if it is made to appear better or of greater value than it really is. (7.) If it contains any added poisonous ingredient, or any ingredient which may render it injurious to the health of a person consuming it.

4. The provisions of this act shall not apply to mixtures or compounds recognized as ordinary articles of food or drinks, provided that the same are not injurious to health, and are distinctly labelled as mixtures or compounds. And no prosecutions shall at any time be maintained under said act concerning any drug the standard of strength or purity whereof has been raised since the issue of the last edition of the United States Pharmacopœia, unless and until such change of standard has been published throughout the Commonwealth.

5. The State Board of Health shall take cognizance of the interests of the public health relating to the sale of drugs and food and the adulteration of the same, and shall make all necessary investigations and inquiries in reference thereto, and for these purposes may appoint inspectors, analysts and chemists, who shall be subject to its supervision and removal.

Within thirty days after the passage of this act the said Board shall adopt such measures as it may deem necessary to facilitate the enforcement hereof and shall prepare rules and regulations with regard to the proper methods of collecting and examining drugs and articles of food. Said Board may expend annually an amount not exceeding ten thousand dollars for the purpose of carrying out the provisions of this act : provided, however, that not less than three-fifths of said amount shall be annually expended for the enforcement of the laws against the adulteration of milk and milk products.

6. Every person offering or exposing for sale, or delivering to a purchaser, any drug or article of food included in the provisions of this act, shall furnish to any analyst or other officer or agent appointed hereunder, who shall apply to him for the purpose and shall tender him the value of the same, a sample sufficient for the purpose of analysis of any such drug or article of food which is in his possession.

7. Whoever hinders, obstructs, or in any way interferes with any inspector, analyst, or any other officer appointed hereunder, in the performance of his duty, and whoever violates any of the provisions of this act, shall be punished by a fine not exceeding fifty dollars for the first offence, and not exceeding one hundred dollars for each subsequent offence.

8. The State Board of Health shall report annually to the Legislature the number of prosecutions made under said chapter, and an itemized account of all money expended in carrying out the provisions thereof.

9. An inspector appointed under the provisions of said chapter two hundred and sixty-three of the acts of the year eighteen hundred and eighty-two shall have the same powers and authority conferred upon a city or town inspector by section two of chapter fifty-seven of the Public Statutes.

10. Nothing contained in chapter two hundred and sixty-three of the acts of the year eighteen hundred and eighty-two shall be in any way construed as repealing or amending anything contained in chapter fifty-seven of the Public Statutes.

11. Before commencing the analysis of any sample the person making the same shall reserve a portion which shall be sealed ; and in case of a complaint against any person the reserved portion of the sample alleged to be adulterated shall upon application be delivered to the defendant or his attorney.

PETROLEUM DISEASE.—A French journal states that the refiners of petroleum—those especially who clean out the apparatus which has been used in the final rectification—are subject to a peculiar skin disease resembling the cancer of chimney sweepers.

SALT OF THE EARTH.—It has been reckoned that if the whole ocean were dried up, all the water passing away as vapor, the amount of salt remaining would be enough to cover 5,000,000 square miles with a layer one mile thick.

LIFE PRESERVER.—An automatic life-saving belt has been tried in the Thames. It can be screwed up like a ball and fired from a cannon or thrown by hand, the belt righting itself by contact with the water.

INDUSTRIAL EDUCATION.

WHAT IS THE BEST SYSTEM FOR BOYS TO LEARN TRADES ?

Considerable of our space for some time past has been given to those who wished to discuss the correlated questions of trade teaching in schools, and that of apprenticeship. We have thought it best to allow considerable latitude in this discussion, for the reason that we thought it desirable to ascertain, so far as possible, the direction in which the thoughts of practical men—the men most interested in these matters—were tending. The thing which, it seems to us, has been most clearly brought out by this discussion is that, so far as mere speculation goes in such a matter, little or nothing can be determined by it. No such industrial university as is proposed by Professor Sweet has ever been tried, and until it is tried the question of its success or failure cannot be determined. It is a matter to which Professor Sweet has devoted a great deal of thought, and no one who is at all acquainted with him will for a moment doubt but that this thought and the article which is the outcome of it were inspired by the very highest and best of motives. It has provoked criticism, which, of course, was expected, and, in fact, desired. Some of the arguments brought against it seem strong, but the question of the success or failure of such a school can only be settled by a trial, and such a trial can be made only when men having money to spare become interested in it, and therefore willing to spend their money for it. To our mind the question is not so much whether the school plan is or is not better than the old system of apprenticeship by indenture, as what can be devised that will enable boys adapted to the machinists' and kindred trades to find opportunities for learning them systematically and thoroughly. At present the situation is simply chaotic. It is extremely difficult, if not impossible, for any one to accurately define the term machinist—define it so that no one can dispute the accuracy of the definition. And in our opinion no plan will ever be devised for acquiring the skill and training necessary to be a real machinist that will be so good as an apprenticeship in a regular commercial machine shop. But that fact signifies little if we have lost the institution of apprenticeship, for if such a loss has occurred then the only question is of a substitute. But it is to be remembered that, no matter what may be said to the contrary, the institution of apprenticeship is not completely gone so far as it applies to the machinist's trade in this country, for there are a number of the very best shops in which apprentices are regularly employed. It is true that the system has greatly declined, but, so far as machinists' apprentices are concerned, this is due solely to changes in the methods of doing work which make apprentices unprofitable to employers, and at the same time makes it difficult if not impossible for boys to get such experience and training as will make them real machinists. But this applies only in such shops as have been able to minutely subdivide and classify the work, keeping each man confined to a certain part of it. Apprentices are out of place here, but, generally speaking, real machinists are equally so. If these two facts were better understood we would be in better shape to arrive at a solution of the question. There are many smaller shops and departments of the larger ones where boys can learn to be good machinists, and if every employer would in such shops or departments employ just as many apprentices as he could do justice to and no more, taking pains to select the best boys, and then treating them well, it would, we think, prove mutually satisfactory. A machine shop is, and always will be, the best place to learn the machinists' trade, but a factory is no place to learn it, even though machines are manufactured in the factory. In the tool room of a modern sewing machine factory, for instance, a boy might learn to be an excellent machinist, while

in the factory itself he could not; but an important fact to be considered along with this is, that real machinists do not work in the factory, save in some exceptional instances, and apprenticeship is not needed to supply workmen for it. This applies to other work in varying degrees, depending upon the extent of the application of the factory methods of manufacture. When the genuine machine shop is provided with boys having an ambition to become genuine machinists, it should be remembered that, while there should be some agreement as to terms, length of service, etc., there is little to be gained by attempting to retain a boy who really wants to leave. Boys should be selected after a preliminary trial to determine if there is a mutual desire to enter into a contract. Thus the right kind of a boy can usually be selected, and things should then be so managed as to make him see that his interest lies in doing his best, and staying his term out. If this and his own sense of honor do not hold him, he is not worth holding. And in this connection it should be remembered that, with an honorable and ambitious boy, the employer's interest lies in the direction of advancing him as fast as possible, and making him a skilled mechanic as much in advance of the expiration of his term as possible. Both parties will thus get the best results from the apprenticeship. Attempts to teach trades in factories, refusal by proprietors to teach them in machine shops, and careless selection of boys to be taught, are more than anything else responsible for the decline of the apprentice system, and it can be revived by avoiding these things. The experience of a number of the best shops in this country proves this. But if apprenticeship is to die out the experiment of a genuine trade school should be tried, and such a trial would be interesting, whether apprenticeship is to die out or not, and it would probably succeed just in proportion as it deserved to succeed.—*American Machinist.*

ASTRONOMICAL PROGRESS.

GRADUAL GROWTH OF A CATALOGUE OF THE STARS.

The improvements made in photographic processes during the last twenty years have made possible discoveries and advances in astronomy so important as to create an epoch in the history of this science. The high sensitiveness of the dry plates invented by the Englishman, Meddox, in 1871—since the new and simplified process of developing the plates was introduced, which gives a clearly defined and undistorted image—permits of the substitution of the photographic method for direct observation with the eye. One advantage is that the personal equation due to subjective errors of the observer is eliminated. A greater advantage is the circumstance that on sufficiently long exposure a very faint object leaves an impression on the plate much more distinct than the sense of sight can appreciate with the most prolonged gaze. The eye can be trained to perceive certain differences in the illumination of neighboring parts, but the limits of its capacity are soon reached; whereas photographs depend on the quantity of light falling on the plate, and by length of exposure the impression can be made as sharp as is desired. And further, the scintillation or twinkling of the stars, caused by the movement of the air, has much less effect on photographs than upon the eye when the object observed is only faintly visible. The scintillation causes a vagueness of outline in the photograph, but the mean position of the star is the darkest point of the picture, which allows of a sufficiently accurate measurement. A huge task accomplished by the aid of photography was the cataloguing of all the stars down to the eleventh magnitude. About 3,000,000 stars have been mapped by means of photographic plates, and it is proposed to extend the work so as to include all above the fourteenth magnitude, of which there are between 30,000,000 and 40,000,000. On the plates innumerable stars are shown in regions of the heavens where not one can be descried with the naked eye. The value of the plates can be seen when it is understood that some of the chief problems in astronomy have relation to the changes in the positions of the stars, and that the maps of zone divisions, that have hitherto furnished the data for calculations, contained only about 200,000 stars. New photographs taken at the end of a hundred years, and compared with those made now, will widen immensely the field of astronomical knowledge. The work has been in progress since 1887, when a congress decided on the plans, and divided the task between twenty-three observatories. The photographic method of determining the forms of the nebulæ is of equal value. The nebulæ we suppose to be worlds in the process of formation. Spectral analysis shows us that to a large extent they are composed of enormous masses of gaseous matter, with which vast regions of the universe are filled. Of their shapes and transformations we know little. Drawings made by different observers vary to such an extent that they can scarcely be identified. One of the finest is the nebula of Andromeda, which has lately been taken by Roberts on a plate exposed for four hours. Whereas the drawings gave no idea of the nature of this formation, we can see at once by the photograph that we have here a body resembling Saturn—bright rings encircling a nucleus of firmer matter. It is a world in the same condition that our solar system, many thousands of years back, was in, according to the theories of Kant and Laplace. With the help of photography we can learn the true shape of the nebulæ, and by comparing pictures taken many years apart, we shall be able to discover whether they undergo changes of form. A third part, of great importance, played by photography, is that of determining, in conjunction with the method of spectral analysis, the rapidity of the movements of stars within the radius of vision—an idea suggested by Prof. Vogel, of Potsdam, who has instruments for taking the measurements for some fifty-five stars. We can now measure the speed of the motion down to a single mile. Since the end of the last century astronomers have studied the movements of stars in relation to the solar system, but only a few stars of which the parallax was known admitted of such a calculation. The direction of the movement could be determined by a great number of observations, but the new method first gave us the rate of velocity. In observing the spectrum of the stars Vogel uses a prism of high dispersive powers. Attempts to obtain lines with the grating, which possesses a much greater resolving power than the prism, have failed, owing to the faintness of the stellar spectra. The spectroscope with grating is found very useful, however, in measuring solar movements, such as the development of protuberances, the velocity of rotation, etc. The rapidity of motion observed in the material constituents of the sun is something enormous. The swiftest storms on the earth's surface travel at the rate of thirty or forty metres a second, whereas on the sun prominences are generated that often rise to the height of 20,000 miles in a quarter of an hour, presenting a velocity of 150 to 300 kilometres a second. Important conclusions have been reached by Wilsing, in Potsdam, in regard to the faculæ, which he has subjected to a close examination. It is known that the surface of the sun, when viewed through the telescope, presents an uneven appearance. Pores, spots, and faculæ are distributed over the sun's surface with tolerable regularity. The sun spots and the faculæ afford the most important evidence regarding the physical nature of the sun and the period of rotation. Late observations have shown the remarkable fact that different parts of the sun's surface have various periods of rotation. Wilsing, by measurements of faculæ on photographs, has found that in all the regions where the faculæ are found the velocity is the same, and calculates the time required for a complete rotation at 25 days 5 hours and 47 seconds. Concerning the nature of the faculæ he draws the conclusion that they have their origin in the lower depths of the solar atmosphere, and indicate the seat of the forces that give rise to the metallic prominences and the sun spots that form later.

LIFE AND ITS CONDITIONS.

WHAT IS IMPLIED BY HARMONY WITH THE ENVIRONMENT.

The above phrase, which is the corner-stone of the modern evolutionary philosophy, is at the same time a mere truism, as applied to living organisms. Life and the conditions of life must necessarily be co-existent, and the question of the variation of existing forms of life to meet the conditions of a changed environment, or to put themselves more in harmony with the environment already existing, is the one of the most importance in any discussions of theories of evolution. To many evolutionists the shape and action of every limb and organ, the color of every feather, the form of every leaf, all indicate the attempt of the animal or plant possessing it to put itself more in harmony with its environment, or, in other words, the minutest detail of bodily structure is of definite use to the organism in performing the two great functions of its existence, nutrition and reproduction. Without discussing any of these minor points, interesting and important as they are, it may be interesting to consider certain widespread and universal examples of the adaptation of living forms to surrounding conditions, which are often overlooked from their very universality. All terrestrial animals and plants are constantly surrounded by a gaseous form of matter, composed of a mixture of nitrogen and oxygen. We have no reason to believe that its composition has been materially different since the time when we note the first indications of life on our globe. It is exactly adapted to sustain the vital processes of the organisms living in it. An atmosphere of pure oxygen or pure nitrogen would cause the death of any animal immersed in it, but the proportions in which they are mixed are exactly right, and the small amount of carbonic acid present is exactly what is needed for the wants of growing vegetation. Nearly every other gas known is either corrosive, irrespirable or poisonous, but the air is practically a neutral, harmless body with its active oxygen so diluted by the inert nitrogen, that the oxidizing processes in the bodies of animals take place with just the proper rapidity to enable them to pass through their life cycle under the most favorable circumstances for themselves and their descendants. It is evident that this adaption of the air to the needs of the animal organism must necessarily exist, otherwise all animal life would have perished at the moment of its coming into existence, but every teaching of science shows that the air was in existence before animals, and as it could not have changed its composition to meet the needs of an organized being, however introduced, it is certain that the form and nature of these beings, if modified at all, must have been modified in a way to meet the conditions demanded by the air. The lowest forms of life can better withstand change in the composition of the air, and to account for the harmony between animals and plants and the atmosphere in which they live the inference is almost irresistible that in the gradual development and modification of inferior forms, each succeeding generation, however it might change in other ways, always retained those organs and functions which were best fitted to utilize the previously existing properties of that mixture of oxygen and nitrogen gases surrounding them. Assuming the existence of life in the first place—and its origin and nature is a mystery about which we know nothing, and which we fear can never be penetrated—we cannot but believe that if the atmosphere had been composed of chlorine, or even if the present gases instead of being mechanically mixed had been chemically combined into nitrous acid, that organisms would have been developed

capable of existing in these corrosive gases, and that to the man living under such conditions the chlorine or nitrous acid would seem as bland and harmless as the pure air of ocean or mountain does to us. Next to air, water is the substance which is of the most importance to living organisms. It is a necessity of life, and forms the greater portion of the substance of all animals and plants, but how perfectly adapted it is to its purpose. Although dissolving to a greater or less extent most chemical compounds, its action on animal or vegetable tissues is practically nothing; it is a bland, neutral and chemically inactive liquid, with physical properties which fit it most admirably to enter into the structure and sustain the vital processes of animals and plants, which no other liquid known to us is capable of doing. Who can doubt that the countless generations of living beings on our globe have been so modified and adapted in substance, form and function as to be in perfect harmony, chemically and physically, with this omnipresent liquid with which they are necessarily brought into such intimate connection. Animals and plants were made to suit the water, not the water to suit the plants. A remarkable instance of this is found in the distinction between salt and fresh water animals and plants, each of which lives and flourishes under conditions which would be fatal to the other. Coming to the mineral constituents of the earth, some very striking examples may be found. The salts of calcium are everywhere present, and are entirely harmless, while the elements barium and strontium are extremely rare, and, at the same time, poisonous. Nitrogen gas is present in the air, and the phosphates of lime and magnesia are widely distributed. All of these substances are not only harmless, but necessary to the animal economy, while the closely allied arsenic, antimony and bismuth are unwholesome and poisonous, but are only found in a few scattered localities. Chlorine, in the form of common salt, is met with everywhere, but the salts of its rare chemical brethren, fluorine, iodine and bromine, are, except in medicinal doses, highly injurious to health. If we accept the modern theory of the evolution of the elements from one primitive form of matter, we can see no reason why the water of the ocean might not have contained as much iodide of potassium or lithium as it does of chloride of sodium; that the coral islands, marble quarries and limestone strata might not have been formed of the poisonous carbonate of barium, or even that the atmospheric nitrogen or the phosphates of the soil might not have been replaced by compounds of arsenic or antimony. Under such conditions, life as we know it could not exist; but there seems to be no reason why organisms might not have appeared that could tolerate arsenic, antimony, barium or iodine, as well as they do the present common elements so closely allied to them. While the above considerations are suggested by the theories of development and harmony with the environment, it must be confessed that they are largely of a speculative nature. We can study existing forms of life, their structure, composition, actions and functions, but we do not know the nature, origin or destiny of that life. We are studying a chain, both ends of which stretch into infinity, and whether we can ever attain and comprehend these limits either here or hereafter time only can show. We can only strive after "more light," trusting to the future to make those things clear to us which are now veiled in an obscurity which appears to be beyond the power of the human intellect to penetrate.—*Popular Science News.*

SUPERSTITION.

AN UNREASONING TRAIT OF REASONING CREATURES.

Superstition like prejudice is impervious to logic, and no argument addressed to the reason has any effect upon its power or prevalence. Why is thirteen an unlucky number? What possible connection has the assemblage of thirteen persons at dinner with the death of any one of them during the ensuing year. If fourteen dined together there is certainly a greater chance that one of them would pass away within the twelvemonth than if one less sat at the table, and yet this is not the common estimate. There is not a housekeeper in this city who would seat thirteen at her table without a feeling of regret, and the great majority would not entertain a company composed of that number for any consideration whatever. We recall an instance where a family given to a liberal hospitality had a dining table which seated six on either side and one at each end. Once every week a dinner was given to which twelve guests were invited, the host and hostess occupying the other seats. If one of the persons invited sent a regret a substitute was sought for and secured if possible. But failing in this, a young woman, a poor relative with pleasant manners, living in the family, took the vacant chair, and was supported in the house for no other purpose than to meet this possible need. There have been "Thirteen Clubs" organized to relieve the number of its reputation, but they have utterly failed of their object. We cannot find that those who thus braved the common superstition were cut short in their days on this account. But people cannot insure themselves against the fatal blow, even by a display of unusual courage, and the ranks of the thirteen were broken sooner or later by the assault which none can successfully resist. There are scores of superstitions connected with the moon and its phases. The effect of the "changes" on the weather is a matter of almost universal belief, although the most renowned of our scientists have agreed with Dr. Ick and the celebrated Dr. Lardner that "there is not the slightest observable dependence between them." There is probably not a person in the country who would not, if he had his choice, prefer to catch the first glimpse of the new satellite over his right shoulder, while large numbers are rendered quite miserable if they happen to see the narrow crescent on its first appearance over their sinister side. The prevalent impression that Friday is an unlucky day regulates in many respects the business of the world. Those who are ready to assert that they have no feeling whatever on the subject are very careful in solicitation of patronage for any new enterprise, or in choosing the date of an entertainment or a marriage not to run counter to this popular fallacy. Some years ago an English shipowner, finding that none of his vessels could get off to sea on Friday owing to the feeling among the sailors, determined to cure the madness if he could. He therefore laid the keel of a vessel on Friday, made every contract concerning the construction on Friday, and launched the craft on the unlucky day. He christened the ship with this name, and found an old sea captain called Friday whom he made master for her first voyage. She was loaded for an East India port, and after great difficulty in securing a crew she sailed on a given Friday for her destination. She was never spoken or heard from after the pilot left her. The presumption is that when she encountered her first storm, the sailors, who are proverbially superstitious, became apprehensive and took to the boats, leaving the ill-fated craft to founder in mid-ocean and to perish themselves in like manner. It is singular how one such incident will deepen a prejudice already existing and established in the minds of many, who are otherwise sensible, a connection between two events that can have no possible relation to each other. Two years ago, it is said, a woman afflicted with catarrh visited the Manhattan Eye and Ear Hospital, to be treated for her illness. Dr. Johnson, who at that time had charge of Cabinet D, treated the case, and two days afterward he suddenly died. The patient was relieved by the treatment, but six months from the first date, on a return of the malady, she again sought the institution. Dr. Pond, then in charge, attended her, and in two days after he died of heart failure, as the record states. A week or so ago she again applied for treatment, and Dr. David Phillips prescribed for her. He dined the same day with a friend, went home not feeling very well, and was found dead in his bed the next day. Whereupon the story is published far and wide, and the poor woman is set down as "The Fatal Patient," whom it is dangerous for any physician to treat. And yet no person of ordinary intelligence would see anything very remarkable in the coincidence described. The original "weather prophet" (Mr. E. Merriam) used to print his "cycles" and "heated terms" and "perturbations the sure sign of earthquakes" in this journal during the administration of Gerard Hallock, nearly fifty years ago, and the present editor in chief, too young then to be very patient with people of such vast pretensions, was disposed to make fun of the predictions. One day, to establish the truth of his prognostications, the "Brooklyn Sage," as he was often called, produced a book in which he had recorded as in a diary his presages of the weather, including predictions of storms, earthquakes and special atmospheric disturbances. Mr. Hallock had kept in a drawer the clippings descriptive of all such phenomena, and he was challenged to produce them, and see if they had not been foretold and the account anticipated in this daily record. There were no telegraphs and ocean cables to give instant notice of such occurrences, and if the writer in Brooklyn put down under date of March 4th, "perturbation—probable earthquake in South America," or signs of a hurricane in the China seas," and the slow mail a month or two later brought an account of such upheavals or disaster, the skill of the observer was firmly established. Sure enough, the volume stood the test in a most remarkable manner. Out of twenty-three actual "shakes" in some part of the world, twenty were predicted in the book at the corresponding date. Out of seventeen fierce storms, notable for the damage they had caused on land or sea, fifteen had been predicted. The old man closed his book with an air of triumph, and the veteran editor uttered his mild rebuke of our incredulity. We remembered the saying of an old scientist who ridiculed the faith in dreams, and was asked if none of his ever came true. He answered that in a long life he had waked with the remembrance of over 30,000 dreams. Of these only five came true, and the connection therefore failed for want of evidence. It occurred to us to test the book on its other side, and see how many predictions had been made that had no counterpart in history. So we seized the volume, and fortifying ourselves behind a desk, we turned its pages. Our suspicions were fully verified. There was hardly a day in the whole year in which some atmospheric disturbance was not plainly predicted, so that a disaster could hardly come amiss to the plethoric volume. If twenty of the twenty-three actual earthquakes found a heralding in the book, there were at least 300 heraldings that had no actual following. If fifteen of the seventeen storms were of previous record, there were ten times that number bespoken in the book that put in no appearance. The credit of the prophet went down to zero under that exposure. It is the exceptional coincidences that give birth to the prevalent superstitions and keep them alive in the popular faith.

LIGHTNING'S FORCE.—It has been calculated that the electromotive force of a bolt of lightning is about 3,500,000 volts, the current about 14,000,000 amperes, and the time about 1 20,000 part of a second. In such a bolt there is an energy of 3,284,182 horse-power.

EASY SOLUTION.—The *Northwestern Mechanic* is responsible for the following: A man who wanted to learn what profession he would have his son enter put him in a room with a Bible, an apple and a dollar bill. If he found him, when he returned, reading the Bible, he would make a clergyman out of him; if eating the apple, a farmer; and if interested in the dollar bill, a banker. When he did return, he found the boy sitting on the Bible, with the dollar bill in his pocket, and the apple almost devoured. He made a politician out of him.

NERVES AND NARCOTICS.

A CAUTION AGAINST RESORTING TO STIMULANTS AND SOPORIFICS.

In the May number of the Breslau *Deutsche Revue* Dr. Adolph Seeligmuller discusses the universal subject of nerve troubles as follows: Excessive, exhausting and too long-continued work, insufficient or irrational recreation, and deprivation of the right amount of sleep are some of the main causes for the increase of nerve troubles in our day. The competition in all the professions and callings is so great that for every person whose powers fail, ten are ready with fresh strength to perform the same or greater labor for the same or even a smaller remuneration. All exciting and weakening amusements should be done away with, and the quiet joys of family intercourse, the conversation of intimate friends, and sociable walks in the fields and woods should take the place of brilliant evening assemblies. Then every person should pursue some agreeable occupation beside his regular profession, and in the latter he ought to have frequent hours of relaxation to relieve the strain. Mental application, even for healthy adult persons, ought not to be continued for more than three or four hours at a time, and night work it would be best to avoid altogether, as the excitement is apt to interfere with sleep. All who follow intellectual pursuits ought to have several weeks of complete rest at least once a year. Sleep is, however, the principal agent of recuperation. The amount of sleep needed is different for different persons. For the ordinary worker from six to eight hours is absolutely necessary; yet how often, in the battle for existence in our time, is the desire for sleep forcibly suppressed and the night's rest improperly shortened. Sooner or later insomnia wreaks its vengeance on the offender. Many a person who once robbed himself of the necessary amount of sleep would gladly sleep now, but cannot. I do not hesitate to say that nerve troubles first develop into disease when joined with sleeplessness. It appears as a later symptom of a long-standing nervous disturbance, but to the lay mind it appears as the first signs of disorder, and is frequently taken to be the cause. The worker of the nineteenth century works beyond his strength, and in order to keep it up he resorts to stimulants—coffee, tea, spices, alcohol, tobacco. These produce a superexcitation of the nerves, which brings in its train insomnia; and to overcome this he resorts to narcotics. The life of many of our contemporaries consists in taking artificial stimulants to enable them to perform their work, and then resorting to powerful narcotics that can counteract the artificial stimulation and produce rest and sleep. Any one can see that this alternation of stimulation and depression at least once every twenty-four hours must weaken the nervous system. Coffee is a powerful stimulant for the heart, nnd, therefore, those who suffer from palpitation, from hysterical conditions, or from insomnia should avoid its use. Tea in day time acts more mildly on most people, but taken evenings it drives away sleep. The spices are less active nerve stimulants; yet pepper, especially, and some of the others affect the nerves of the digestive organs powerfully, and their liberal use in modern cookery has something to do with the epidemic insomnia. Of the injurious, the actually destructive effects of alcohol taken in excess little need be said. We physicians are not a little to blame in that we insist on giving large quantities of alcohol in fevers and conditions of exhaustion, not to speak of the methods used to cure the morphine habit, until patients often acquire the drinking habit. The evil results of the abuse of alcohol are not often apparent. Long before *delirium tremens* or other serious brain diseases appear, they are preceded by manifold nervous disturbances, the real cause of which is not often understood. I have frequently found that rheumatic pains that were ascribed to a cold were nothing but alcohol neutritis, a mild form of inflammation of the nerves resulting from the use of alcohol, which disappeared when the practice was given up, only to return with the slightest repetition of the indulgence. Most habitual drinkers, and some of them very early, are subject to changes in the vascular organs, such as fatty degeneration of the heart and arterio-sclerosis, which lead to grave affections of the nervous system, like apoplexy and softening of the brain. Finally, it may be taken as proven that the children of drunkards, if they are not carried off prematurely by brain troubles, are frequently afflicted with serious nervous ailments, such as epilepsy, idiocy and the like. Tobacco has come to be in our time a national poison in many countries, and most especially in Germany. As sequels of chronic nicotine intoxication may be noted without fear of contradiction: Palpitation and weakness of the heart; irregularity of the pulse, of which heart-pang or *angina pectoris* is an acute symptom; general nervous debility; tremulousness; disturbances of vision even to the point of blindness; and hypochondriacal depression even to the degree of melancholia. The fear-inspiring intermission of the pulse is a frequent cause of inveterate insomnia. That the children of heavy smokers suffer with uncommon frequency from nervous diseases is an established fact. And now for the narcotics, at the head of which stands morphine. The great danger of falling into the habitual use of this drug arises from the cowardice and degeneracy of our times. No one will suffer pain, no matter how slight or transitory. Not a tooth can be drawn, not a child born into the world without the use of an anodyne, and when death comes we must have enthanasia. It is said that many physicians lend their hand too willingly and are ready with the injecting needle to check a pain that could easily be borne, not reflecting that it is immoral to encourage effeminacy and a dangerous thing to plant the germ of the morphine habit, a terrible passion that leads inevitably to physical and spiritual debility and to death. The same is true of the constantly increasing cocainism and hasheesh intoxication. Our generation demands above everything narcotics to produce the sleep that first we drive from us, and afterward so fondly desire: opium, morphine, chloral, bromide of sodium, paraldehyde, hydrate of amyl, urethan, sulfonal, hypnon, somnal, and whatever are all their names—one would think names would soon give out, so fast are these children born. But how can we sleep without resorting to soporifics? Just as the life of the soul during the day is reflected in dreams, so the conditions of sleep are determined by all that we do when awake. The chief rule is to so act waking that you can sleep. Begin by accustoming yourself to do without excitants. Many a case of sleeplessness I have seen yield, when all other means failed, to restricting or totally abandoning for a time the use of spirituous drinks, coffee, tea and tobacco.

WORKS BOTH WAYS.—A Broadway druggist has a large, inviting silver-plated machine for registering weight. People come in to make purchases, and while the clerks are filling their orders they step on the scales. To the right of the scales is a small table covered with pamphlets entitled "How to Get Thin." On the other side is a similar table on which there are a lot of books labeled "How to Increase One's Weight." No man ever gets off the scales without deciding that he is either too fat or too lean, and naturally selects a book which recommends a pill, and the pills cost $2 a box. If the visitor be too fat he buys a box having a blue label, and if he is too thin he takes a box of a reddish tint.

HIGHEST PLACE.—The highest place in the world regularly inhabited is the Buddhist monastery, Halne, in Tibet, Asia, which is about 16,000 feet above sea level. The next highest is Galera, a railway station in Peru, South America, which is located at a height of 15,635. Near it, at the same level, a railway tunnel 3,847 feet long is being driven through the mountains. The elevation of the city of Potosi, in Bolivia, South America, is 13,330 feet; Cuzco, Peru, 11,380 feet; La Paz, Bolivia, 10,883 feet; and Leadville, Col., 10,200 feet.

DOMESTIC DIETETICS.

SPECIALLY PREPARED, FROM PRACTICAL TESTS, FOR THE LADY READERS OF THE "AMERICAN ANALYST."

SEASONABLE FOOD.
July.

MEAT.—Beef, lamb, mutton, ham, kidneys, liver, sausage, veal.

GAME AND POULTRY.—Pigeon, chicken, duck.

FISH.—Anchovy, bass, bluefish, blackfish, cod, eels, clams, flounder, haddock, halibut, herring, lobsters, mackerel, mussels, perch, porgie, prawn, salmon, shad, turtle, trout, sturgeon, whiting, weak-fish.

VEGETABLES. — Beans, cucumbers, carrots, cauliflower, egg-plant, lettuce, onions, parsley, parsnips, potatoes, shallots, spinach, turnips, radish, rhubarb, corn, beets.

FRUITS.—Cherries, strawberries, raspberries, huckleberries, melons, gooseberries, blaekberries, peaches, pears, tamarinds bananas, pineapples.

PRACTICAL RECIPES.

FRENCH TOAST.—To a cup of milk add a well-beaten egg and a little salt. Cut some slices of bread rather thick, trim off the crust, make the slices the same size, dip them into the milk and fry to a light brown in boiling lard.

BARLEY BROTH.—Put a pound of mutton or beef to cook with half a pound barley and four quarts of water, boil for an hour, then add a piece of cabbage, a turnip, a carrot, a piece of parsnip, an onion cut in two, some parsley and a few stalks of celery. Boil for an hour and a half, strain, season, and serve. Add more water if too much boils away.

POTATO PUFF.—Two cups cold mashed potatoes, two spoonfuls melted butter, two well-beaten eggs, a cup of milk, pepper and salt. Beat the ingredients together until they are light, then pour into a buttered baking dish, smooth over with beaten egg and bake a light brown.

GEMS.—Three well-beaten eggs, two cups milk, two cups flour, half a saltspoon of salt. Beat up lightly and bake in gem pans in a quick oven. Serve with cream sauce made as follows: Beat to a cream a cup fine sugar and half a cup butter, add four tablespoonfuls of thick cream, beat very light, flavor with nutmeg and vanilla or brandy.

GOLDEN LAYER CAKE.—One cup sugar, one half cup butter, one half cup sweet milk, two and a half small cupfuls of flour, two teaspoonfuls of baking powder, a little salt, whites of three eggs; flavor with lemon and bake in layers. Beat up the yolks of the eggs, thicken them with powdered sugar, flavor with grated lemon rind, and spread between and on top of the layers.

SAUSAGE RISSOLES.—Have some water boiling in a saucepan. Take a few sausages and plunge them into the water; after they have boiled for a few minutes, take them out, strip off the skins and cut them in two and set them aside to cool. Make some light pie crust, cut it into thin squares of four or five inches, lay half a sausage in each, fold over the edges, brush each rissole with beaten egg and bake a fine brown.

SAUCE FOR CODFISH.—Put in a saucepan a bunch of parsley, a young onion cut in pieces, two cloves and a good lump of butter, cook them together for a few moments, then add a heaping teaspoonful of flour and cook for a moment more; add sufficient cream or milk to make it the proper consistency. Strain, add a little chopped parsley that has first been scalded, and serve.

BOSTON BROWN BREAD WITH CHEESE.—Cut some thin slices of bread and toast them slightly. Butter each slice and cut it into quarters, lay them on a buttered tin and pour a little milk on them; sprinkle with

salt and pepper and cover with Parmesan cheese; brown in the oven for ten minutes. This is a nice breakfast dish.

COCOANUT PUDDING.—To one fresh cocoanut, grated fine, add half a cup of sugar, half a saltspoon of nutmeg and a saltspoonful of salt. Beat thoroughly the yolks of five eggs; add to them four tablespoonfuls of creamed butter; whisk all the ingredients until they are a creamy mass. Pour it into a buttered pudding dish and bake thirty minutes.

STRAWBERRY ICE CREAM.—Hull two quarts of ripe berries and cover them with half a pound of sugar and let them stand for two hours, mash them through a sieve and add more sugar, enough to make a thick syrup then add to it, beating hard all the time, two quarts of cream. Freeze and pack.

HEAT AND ELECTRICITY.—The electricity conducting capacity of various metals ranks as follows: Silver 100; copper 96; gold 72; aluminum 52; zinc 26; platinum 16; iron 15; nickel 12; tin 11; lead 7. Copper and iron are the only metals that have commercial value as electrical conductors. The heat-conducting qualities of the metals range about as follows: Silver 100; copper 73.80; gold 52.20; annealed aluminum 38.87; unannealed aluminum 37.96; tin 14.50; iron 11.90; steel 11.60; lead 8.50; platinum 8.40; bismuth 1.80.

RELIC OF THE PAST.—In Dubuque, Ia., on June 9, Henry Wagner was digging in his garden when he turned up the dirt and rust incrusted blade of an ancient sword. When the crust had been removed a beautifully engraved scroll enclosing the date "1580" was revealed. Above it is the figure of a crouching hound, and still higher a mailed arm and hand clinching a drawn sword. On the other side is engraved what looks like a Papal mitre and a stand of armor with crossed swords and lances. The whole blade is covered with handsome engravings and is of the finest Damascus steel. Although apparently over 300 years old it can still be bent almost double. The weapon is thought to be a relic of the early French explorers who first visited the Valley of the Mississippi.

Exhaustion

Horsford's Acid Phosphate.

The phosphates of the system are consumed with every effort, and exhaustion usually indicates a lack of supply. The Acid Phosphate supplies the phosphates, thereby relieving exhaustion, and increasing the capacity for labor. Pleasant to the taste.

Dr. A. N. KROUT, Van Wert, O., says:

"Decidedly beneficial in nervous exhaustion."

Dr. S. T. NEWMAN, St. Louis, Mo., says:

"A remedy of great service in many forms of exhaustion."

DESCRIPTIVE PAMPHLET FREE.

RUMFORD CHEMICAL WORKS,
PROVIDENCE, R. I.

BEWARE OF SUBSTITUTES AND IMITATIONS.

CAUTION:—Be sure the word "Horsford's" is *printed* on the label. All others are spurious. Never sold in bulk.

BUSINESS NOTES.

CUT THEM OUT.

Original receipts by Maria Parloa, Mrs. Rorer, Amy Barnes, Mrs. Lincoln, Miss Bedford, Marion Harland, Mrs. Dearborn and other adepts in the culinary art will appear in our columns, the first one to-day, page 319. These receipts were contributed to the Cleveland Baking Powder Company and that company is going to use part of its advertising space for their insertion. Housekeepers should not miss one of these practical receipts. Cut them out. They are worthy of a place in your own cook book.

HORSFORD'S ACID PHOSPHATE.

If you are nervous, and cannot sleep, try it. Dr. Chas. H. S. Davis, Meriden, Conn., says: "I have used it as an accessory in cases of melancholia and nervous debility, and as a pleasant and cooling drink in fevers, and have been very much pleased with it." Dr. A. L. Zurker, Melrose, Minn., says: "It produced a gratifying and remarkable regenerating effect in a case of sunstroke."

SAVE THE EYES.—In families where there is much sewing to be done, it is a good plan to have the bulk of work on dark and colored goods done by day-light, preserving the white sewing for the evening, in order to save the eyes.

HYGIENIC EXHIBITION.—An International Hygienic Exhibition will be held in the months of January and February, 1892, in Leipzic. The exhibition will comprise, among others, sections devoted to hygiene, food-stuffs, and ambulances.

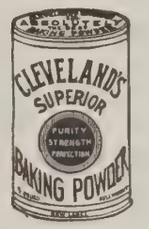
NIAGARA'S POWER.—According to a scientist, the hourly rate of water falling over Niagara Falls is 100,000,000 tons, representing 16,000,000 horse power; and the total daily production of coal in the world would just about suffice to pump the water back again.

HIGH SCIENTISTS.—"In reference to technicalities," says Dr. James Truman, "there is a certain class of scientific men who, in their dealings with their special work, so overload the matter with technical terms that they can never be clearly understood, even by those equally advanced as themselves."

LONDON GROCERS.—Among the clever stories retailed at the Beefsteak or the Garrick, is a nice one of the florid lawyer, who was "counsel in an action for libel brought by a provision merchant against a local newspaper. He said in his address to the jury: 'My client, gentlemen, is a grocer; and the reputation of a grocer in the City of London is like the bloom on a peach. Touch it, and it is gone forever.'"

GRANT'S HUMOR.—Grant and Sherman were discussing the plans of a campaign, when a third general, a brigadier, entered the tent—a good soldier, but notorious for his carelessness as to his personal appearance. The brigadier finished his errand and went out. General Grant pulled upon his cigar for a few minutes in silence, and then said: "Sherman, I wonder whom that man gets to wear his shirts the first week."

DANGERS OF SULPHONAL.—Although sulphonal is probably one of the safest, as it is one of the most efficacious, among the hypnotics recently introduced, the series of cases published by Bresslauer, of Vienna, show clearly that it has certain dangers. The degree of peril is difficult to estimate, as the patients were lunatics, and were also apparently feeble; but the fact is significant that out of seventy-seven patients who were treated with the drug, no less than seven showed serious symptoms, and in five of these there was a fatal termination. It ought to be mentioned that the patients had been taking the drug for a considerable time in good doses, and had borne it well until symptoms of disturbance set in, these being great constipation, bark brown urine, slow or in some cases rapid but feeble pulse, discolored patches resembling purpura on the limbs, and great prostration. In the cases which ended fatally, the case of death was heart failure, with œdema of the lungs.—*Lancet.*



ORIGINAL. No. 22.

Cracknels

BY MRS. S. T. RORER,
Principal Philadelphia Cooking School.

Add to one quart of sifted flour a half teaspoonful of grated nutmeg, one teaspoonful of cinnamon, one of Cleveland's baking powder, a half of salt; mix and rub in four ounces of butter. Add sufficient milk to make a dough. Knead and roll out, spread lightly with soft butter, fold in three, roll out again, and cut with a sharp knife into square cakes. Beat the white of one egg, a tablespoonful of sugar and one of milk together, brush over the tops and bake fifteen minutes in a moderately quick oven.

Use only Cleveland's baking powder, the proportions are made for that.

Cleveland's Baking Powder leavens best because its strength is produced by cream of tartar and soda only, not by ammonia or alum.

25 CTS PISO'S CURE FOR 25 CTS
CURES WHERE ALL ELSE FAILS.
Best Cough Syrup. Tastes good. Use in time. Sold by druggists.

PURE PEPSIN

In Powder and Scale.

MANUFACTURED BY

ARMOUR & COMPANY, Chicago.

Guaranteed free from adulteration or make-weights; of excellent physical properties and high digestive power.

Under similar conditions, **ARMOUR'S PEPSIN** will exhibit greater activity than any other pepsin now before the profession.

The Manufacturers will be pleased to supply members of the Medical Profession with samples of their Pepsin, and with full details regarding digestive strength, if desired.

SEE PAGE 320 FOR VALUABLE OFFER.

WATCHES.

EVERY one wants a watch, and naturally a good watch that keeps accurate time, presents a handsome appearance, and is inexpensive. If such a watch can be found of American manufacture, it is an additional appeal to our patriotism. Just such a watch as this ideal THE ANALYST PUBLISHING COMPANY is enabled to offer as a Premium to its readers. Having some large advertising contracts we have been enabled to procure the movements of the manufacture of the best known American watch factories, namely, the Waltham, Elgin, Hampden and Illinois Watch Companies. These movements are adapted for both ladies' and gentlemen's watches, and are warranted by the makers. These movements have seven jewels, patent lever movement, chronometer balance, patent safety pinion, sunk hard-enameled dial, straight line visible palette, stem winders, hand set; in fact, contain all the latest improvements and can be readily cleaned or repaired by any ordinary good watchmaker. They can be regulated to run as close as any movement.

It is needless to say that to case these movements in solid gold cases would make them too expensive, yet they are cased in what are known as gold filled or stiffened "Ladd" cases, and are warranted to be 14 karat gold, made from two sheets of 14 karat gold overlaying fine composition metal, with regular jointed caps, covers and bezels, and to wear at least five years. They are not plated, nor rolled gold, but actual 14 karat gold cases, thin of course, but stiffened and strengthened by being filled with this fine composition metal. They are finished in the same manner, engine turned and engraved as solid gold watches, and wear and look just the same. No one but an expert can tell them from a solid gold watch. These watches are made both open face and hunting case style, in gentlemen's or ladies' sizes. For gentlemen we recommend plain engine-turned cases; for ladies, a handsomely engraved case.

How to Obtain One of these Watches.

These watches are not to be purchased from us at any price. Send us a club of 25 subscribers to the AMERICAN ANALYST, and $25, the regular subscription price, and one of these watches (your choice of style and size) will be immediately forwarded, post-paid and registered, to your address. You need not wait until you have your 25 subscribers all together, but forward them as you get them and they will be credited to you, and when the number is complete the watch will be sent. A subscription for two or three years will be counted as two or three subscribers.

As these watches are retailed by jewelers at not less than $25, it will be seen that we are offering a real premium with the sole object of increasing our circulation, and that by taking advantage of our offer any one can obtain a good, reliable and handsome watch without cost. As the number of these watches at this price is limited, it is advisable to take steps at once to procure a bargain.

THE ANALYST PUBLISHING CO., 19 PARK PLACE, NEW YORK.

BICYCLES

GIVEN AWAY TO BOYS AND GIRLS!

AN OPPORTUNITY OPEN TO ALL.

The Analyst Publishing Company being desirous of largely increasing their subscription list, will furnish every one with a beautiful Safety Bicycle, ABSOLUTELY FREE, in return for a few hours' canvassing.

To every boy and girl who secures 75 subscribers for the American Analyst at $75, we will give a splendid

$40.00

NONPAREIL

SAFETY BICYCLE.

These bicycles are adapted in size to boys, but are strong enough to carry a man. A boy's bicycle should be a strong one. They are manufactured by the OVERMAN WHEEL CO., the makers of the celebrated VICTOR Bicycle, and have the full guarantee of the makers.

The following is a brief description of the NONPAREIL SAFETY; 26-inch wheels; ball bearing all around, including pedals; solid crescent rims; double tangent spokes; three-fourths inch tires; cranks, three throw, $4\frac{1}{4}$ to $5\frac{3}{4}$ inches; guards to both wheels; tool-bag, oiler and wrench. Finished in bright enamel, all exposed metal heavy nickel-plate on copper.

In selecting these machines as a premium, we have disregarded cheapness and selected a Bicycle which is serviceable, and the makers of which have an established reputation for building the best Bicycle that money, machinery and brains can produce. We are actually furnishing the Bicycles and Papers at less than cost, but hope by stimulating active and successful canvassing, and thus enlarging our subscription lists, to make an eventual profit. We positively guarantee these bicycles to be just as here represented. They will be shipped by express f. o. b. in New York.

Subscription orders must be made out plainly and legibly, and sent as fast as secured, addressed to

THE ANALYST PUBLISHING CO., 19 Park Place, New York.

A VALUABLE BOOK FOR NOTHING.

The AMERICAN ANALYST will send to any person who will forward a New Subscription with One Dollar, a copy of

THE FAMILY CYCLOPÆDIA OF USEFUL KNOWLEDGE.

This is unquestionably one of the most interesting, entertaining and instructive books ever published. It is a universal educator for every member of the family circle, filled with useful information from beginning to end, and this information is given in such an attractive and pleasing way that the book is quite as entertaining as it is instructive. It treats of hundreds of subjects of which no man, woman or child who seeks to be well informed can afford to be ignorant, yet of which the masses of people are entirely unlearned. It contains the cream or substance of a dozen ordinary volumes, and is one of the most valuable and useful books a family can have in the house. No living man is so well informed that he may not learn from it. It is a book for the masses, for old and young, rich and poor, and will be read with pleasure and profit by all. It will likewise be found of great value as a work of reference. The book is profusely and elegantly illustrated, and is conveniently divided into departments, as follows: ***Biography, History, Natural History, Travels, Manners and Customs, etc.; The World Illustrated, Useful Arts and Manufactures, Trees, Plants, Fruits, etc.; Great Inventions, Mining, Wonders of the Sea, Familiar Science, Law for the Masses, Statistical and Miscellaneous.*** All the above subjects are fully and ably treated in this valuable book. It is a vast storehouse of useful and entertaining knowledge—unquestionably one of the best and most valuable books ever published in any land or language. No cyclopædia ever heretofore published at twice the cost is to be compared with this book in point of artistic make-up, beauty, and excellence of illustration, and quality of contents. As a holiday or birthday present for any one, nothing more appropriate or acceptable could possibly be selected. THE FAMILY CYCLOPÆDIA OF USEFUL KNOWLEDGE is a large and handsome book of 544 pages, 12mo, printed upon fine paper and elegantly bound in cloth, embellished with artistic designs in black and gold. It contains ***Two Hundred and Seventy-three Beautiful Illustrations,*** the original cost of which was over $5,000. The book will be sent by mail, post-paid, to any person sending a ***New Subscription with One Dollar.*** It is as large and handsomely gotten up as books usually sold at $1.50 and $2.00, and in the quality of its contents is worth a dozen ordinary volumes.

TABASCO PEPPER SAUCE,

OR LIQUID PEPPER.

Is simply the Pulp of the Ripe Pepper Extracted by Pressure.

The seed of this Pepper was obtained from Central America, and by careful cultivation in Louisiana for many years has been so improved in strength, flavor and aroma, as to have become a new variety of Red Pepper, superior to all others. The pulp is so handled as to retain all the flavor, strength, aroma and color of the ripe fruit, and to keep unimpaired in any climate. It excites the appetite, promotes digestion, and is pronounced by connoisseurs to be the finest condiment in the world. For medicinal purposes it recommends itself by its purity, strength and diffusible form.

Manufactured by E. McILHENNY'S SON,

NEW IBERIA, LA.

For Sale by all Wholesale Grocers.

NATRONA BI-CARBONATE OF SODA.

(ABSOLUTELY PURE.)

The nature of the raw material from which NATRONA BI-CARBONATE OF SODA is made—viz., kryolith, a mineral containing *pure sodium*—insures a purity and uniformity of product which cannot be obtained from any other known material. In making BI-CARB. SODA from any other raw material, the use of sulphuric acid is a necessity, but none is used in any part of the process of making NATRONA BI-CARB.; hence its entire freedom from the slightest trace of arsenic, which is always present in ordinary soda. Its absolute purity and entire freedom from all traces of *sulphate of soda*, common salt and other impurities, render NATRONA BI-CARB. NEARLY TASTELESS, and being bolted through the finest bolting-cloth, insures the finest stage of division.

To these indisputable facts the attention of CONSUMERS of soda is specially called. They are IMPORTANT, and should influence both those who use and those who sell soda, to buy and sell NONE BUT THE BEST.

The NATRONA BI-CARB. Soda is kept in stock by almost every wholesale druggist and grocer throughout the United States, of whom it may be ordered.

Natrona Bi-Carb. Soda is unequaled by any other brand of English or American Manufacture.

INSTRUCTIONS TO SUBSCRIBERS.

The **Names of all Subscribers** are registered as soon as received, and paper is always promptly forwarded.

Postage.—The postage to all parts of the United States and Canada is paid by the publisher.

Remittances of small sums may be made with comparative safety in ordinary letters. Sums of one dollar or more must be sent by registered letter or P. O. money order, otherwise we cannot be responsible for same. Silver must not be sent in a letter.

Postage Stamps will be received for the fractional part of a dollar, and in any amount when it is impossible for patrons to procure bills, but you must send one or two-cent stamps only.

SUBSCRIPTIONS.—The AMERICAN ANALYST will be sent one year to any subscriber for ONE DOLLAR. New subscriptions can begin at any time.

We Stop the Paper at the expiration of the time paid for unless a renewal of subscription is received. Those whose subscriptions have expired must not expect to continue to receive the paper unless they send the money to pay for it.

Change of Address.—Subscribers wishing their addresses changed must invariably give their former as well as new address.

Missing Numbers.—It occasionally happens that numbers of our paper sent to subscribers are lost or stolen in the mails. In case you do not receive any number when due, write us a postal card and we will cheerfully forward a duplicate of the missing number.

Most Important of All.—In every letter that you write us, never fail to give your full address, plainly written—name, post-office, County and State.

A PURE FOOD ASSOCIATION.

The two meetings which have been held at the Mercantile Exchange, in Harrison street, within a few days, for the purpose of forming a Pure Food Association have been incorrectly reported in the daily papers. The object of the gentlemen who were present at those meetings may have been originally to form such an association, but wiser counsels prevailed and the matter was left in a somewhat chaotic state. It was found to be impossible to establish any mutually acceptable standard as to what constitutes purity. No two manufacturers could agree as to where the line between purity and adulteration should be drawn, as what one man might consider pure another would condemn as sophisticated. It was found that the definition of adulteration in a legal sense was something entirely different from the commercial signification of the phrase. There were illustrations brought to bear upon the subject which proved clearly that what the law defined to be an adulteration was an absolute necessity in the preparation of some food products to prevent their becoming noxious. Another difficulty in the way was found to be the readiness and anxiety shown by manufacturers of questionable food products to range themselves alongside of well known manufacturers of the highest grade of pure foods, thus to enable themselves to parade before the public as in good company. Another danger point was found in the tendency of some to switch a really well intended movement on to a side track of an advertising show, or simply a money making scheme. There are enough manufacturers of high grade food products of unquestioned purity who are ready to go into any movement which can prove to them that the enterprise is honestly designed and bears on its face a probability of practical success. But naturally they will be beset by men who have their little axes to grind. Such a movement, if kept strictly to its prime object and honestly and faithfully managed, would be and deserves to be a success. Though yet only in an embryo state we understand the plan is to form an incorporated limited liability company with a sufficient capital to give exhibitions of the products of the members only, and thus educate the public up to a clear apprehension of what pure, first-class food products are, and to teach them that such goods are intrinsically cheaper than adulterated goods at nominally lower prices, and to stimulate emulation among competing manufacturers. It is proposed to hedge this about with safeguards, by limiting the amount of stock held by individual members, making it possible for the management for cause to cancel membership and buy back the stock, exercising a strict censorship over admission of members, etc., practically on the lines laid down and advocated for the past seven years by the AMERICAN ANALYST.

AN EARNEST MISSIONARY.

There arrived in this city a few weeks ago by steamer from Liverpool, a devoted woman who was returning from a missionary tour of the globe, of a character that probably has no parallel in the records of foreign mission labor. Mrs. Mary Clement Leavitt, of Boston, left this country eight years ago with a steamship ticket in her pocket and a plentiful supply of faith. She was a member of the Women's Christian Temperance Union, and at the National Convention of the organization in 1883 it was decided to send out a world missionary. Volunteers were asked for, and Mrs. Leavitt was the first to apply. She was accepted. It was understood that the association would pay all the expenses of the trip, and before the Convention adjourned $1,000 had been subscribed. She determined not to accept it. "I'm going on God's mission," she said, "and he will carry me through." She purchased her steamship ticket with her own money. Very little has been heard of her since she went away. Occasionally a letter was printed in the organ of the association telling of her progress. There was great rejoicing a month ago when a letter brought the news that she had nearly completed her journey and would be home again. Mrs. Leavitt will remain in Boston until October, when she will come to New York to attend the national Convention. In the eight years she has been away Mrs. Leavitt has visited the following places: Hawaiian Islands, New Zealand, Australia, Tasmania, Japan, China, Siam, Straits settlements (Singapore and Malay Peninsula), Burmah, Hindostan, Ceylon, Mauritius, Madagascar, Natal, Orange Free State, Cape Colony, England, Ireland, Scotland, Wales, Congo, Free State, Old Calabar, Sierra Leone, Madeira, Spain, France, Holland, Norway, Sweden, Finland, Denmark, Germany, Italy, Greece, Egypt, Syria, and Turkey. She has organized 86 W. C. T. U's, 24 men's temperance societies, mostly in Japan, India and Madagascar, and 23 branches of the White Cross; has held over 1,600 meetings; has traveled nearly 100,000 miles, and has had the services of 229 interpreters in 47 languages. Her expenses have been paid with money donated to her at the places she visited.

FRENCH SARDINES.

It is stated in an official report from Bordeaux, lately published, that last year's season was one of the most disastrous ever experienced by French sardine packers. Hardly any stocks had remained from the previous year, and the demand was active at the commencement of 1890; but, unfortunately for the packers, the cool summer had a prejudicial effect upon the results of the fishing, and high prices had to be paid for the small quantities of fish which were to be obtained for preserving. Under other circumstances this state of things would have caused a rise of 50 per cent. perhaps in prices at Bordeaux; but France has for some years already lost the monoply of the sardine-packing industry, and the Portuguese factories last year again furnished a more than sufficient supply towards making up for the deficit in the French output. While the average cost of the fish on the French coast was about $4.00 per thousand, the averge price last year on the Portuguese was only about 75 cents. It is thus evident that the French sardine packers were unable to contend, or at all events, to derive a profit from their business, against such an overwhelming competition. The sardine syndicate has come to nothing.

AN OVERFLOWED DESERT.

A phenomenon that at this writing has not been accounted for is reported to be manifesting itself in California. The Colorado desert in San Diego County is well known as an inland depression 270 feet below the level of the sea in its deepest part, and covering an area of 3,000 square miles. On the evening of June 27 the workmen at the great salt works at Salton were amazed to see streams of water trickling down the val-

ley. These increased in size until for several miles around the earth was covered by a shining lake of salt water thirteen inches in depth. On June 30 the water was fifteen inches deep. The current shows the water is coming from the direction of New River, which receives its water from the Colorado. The theory of those familiar with the desert is that an earthquake or some other convulsion has forced an underground artesian stream of water up through the sandy soil. This tract bears evidence of having been flooded many years ago, and Indian tradition declares that a great inland lake stretched at one time from this region to the San Jacinto Mountains, that separate the desert from the orange groves of San Bernardino County. The Southern Pacific Railroad passes through the basin more than fifty miles, its lowest point being 263 feet below the sea level. The Colorado River is 160 feet above the sea level at Yuma. If the subterranean passage connects with the Colorado above Yuma the lake will be over four hundred feet in depth and over fifty miles long. If the waters continue to rise the Southern Pacific track will be submerged nearly one hundred miles, and the great desert of Colorado will be converted into a vast lake.

BENEFICENT BACTERIA.

THE INTERDEPENDENCE OF LIVING ORGANISMS.

We are so much accustomed to regard bacteria as the most dangerous foes of humanity, that the attempt to demonstrate their utility and essential importance may seem almost paradoxical. Nevertheless, it would be as unjust to condemn the whole class for the diseases engendered by a few as to condemn humanity for the offences of its criminals. As a matter of fact, the services of bacteria in the natural economy of the earth are so important that disease germs may fairly be regarded as isolated, scattered bands. The elimination of the bacteria from the earth would be immediately followed by our own downfall. Refuse would accumulate in piles mountains high, while the plants that depend upon it for the greater part of their sustenance would perish in sight of plenty from the want of microbes to convert it into assimilate food. Every trace of organic matter is greedily seized on by microbes, which convert it into plant food or decompose it into its original elements, and thus render the earth continuously habitable for man and beast. These bacteria are so small that a million of them may constitute a mass hardly visible to the naked eye; nevertheless, such is their capacity for increase, under favorable conditions, that the progeny of a single bacteria, if it could multiply unchecked for fifteen days, would constitute a mass exceeding the cubic contents of the ocean. Their increase is arrested only by failure of food supply; they are consequently always in sufficient numbers for the conversion of all the dead organic matter of the earth into food substance for living plants. The manure which the farmer spreads on his fields contains billions of these industrious laborers, all actively engaged in converting the organized elements into plant food, and even in rendering the inorganic substances (lime, potash, phosphates, etc.) assimilable. The most important soil constituents for the farmers are the nitrogenous compounds, the presence of which in manure constitutes its prime value as a fertilizer. Plants take nitrogen from the air; they must take it up by their roots from the soil, but nitrogen is not a proper constituent of soils. In a state of nature the soil gets a supply from the substance of the plants and animals that die on its surface, but grain crops soon exhaust this natural supply, and the fertility of the soil can only be maintained by the addition of nitrogenous substances, which the bacteria, in pursuit of their own well-being, convert into assimilable plant food. But experience has taught the farmer that while grain and root crops exhaust the soil of its nitrogen, beans, peas and other leguminous plants, so far from exhausting, add to its supply, thus rendering possible a high cultivation by rotation of crops, with considerable economy of manure. But these leguminous plants are no more capable than others of drawing their nitrogenous supply from the atmosphere; modern investigation has demonstrated that it is the work of bacteria which finds sustenance and habitation in the roots of the leguminous plants, where they multiply from generation to generation, repaying the service by dying there and sacrificing to the plant all the nitrogen they have taken from the atmosphere in assimilable form. The little swellings on the roots which constitute at once their dwelling place, laboratory and tomb may be readily recognized on removing an acacia, or mimosa, or other leguminous plant from the pot in which it is grown. Not less beneficial are the bacteria as purifiers of water. If a vessel of water containing animal or vegetable refuse is allowed to stand in the open air, the fluid gradually clears until every particle of dead organic matter is consumed, when the bacteria cease their activity and sink to the bottom. The same thing occurs on the great scale in nature: the Seine, which at Paris receives an enormous amount of refuse, is clear and pure at seventy kilometres down stream. The bacteria have consumed the refuse. The Elbe, the receptacle of the refuse of so many cities, is drinkable at Hamburg from the self same cause. The relation of mutual interdependence subsisting between leguminous plants and the microbe guests of their roots, scientifically characterized as a *symbiotic* relation, exists between other plants and microbes. A precisely similar relation exists between a fungus and plants growing in soils rich in humus, which consequently require special treatment under cultivation. The heaths, rhododedendrons, daphnes, etc., growing in such soils support a thread fungus on their roots, which reciprocates the service by supplying the plants with nitrogen, and if the gardener would cultivate them successfully he must import the soil as well as the plants, and be careful, moreover, not to allow the soil to dry lest the fungi die. The lichens and algæ, insignificant and lowly as they seem, play a very important role in the economy of nature. They sink into insignificance when the conditions are favorable to the support of higher vegetation, but the task is theirs to create the conditions necessary to the growth of higher plants. Ascend the mountains or penetrate into high latitudes to the boundaries of eternal snow, and every rock is found covered with lichens, the support of the reindeer, and commonly, but improperly, called reindeer moss. With its slender filaments it mines a foothold for itself in the solid rock; the carbonic acid which it secretes, being dissolved in water, sets free the nilic acid, and in this way decomposes granite, gneiss, micaceous shale, etc. Its remains, in course of decomposition, afford sustenance for mosses, and in this way the solid rock is decomposed into plant-supporting soil. The imbauba tree (*cecropia*), of Brazil, exhibits an interesting instance of *symbiosis* between the tree and a species of small black ant which subsists on it, and keeps watch and ward on every branch. The leaf-cutting ant which inhabits this region has a strong partiality for imbauba leaves, and but for its defenders would attack it so energetically that it would soon become extinct; but woe to the leaf-cutting ant that would essay to cut a leaf of the imbauba tree! The examples selected are prominent instances of the absolute interdependence of certain organisms, and suffice to suggest the idea of a common interdependence of all living organisms. Each is dependent upon the others for the gratification of its needs. No one great section of life could be eliminated without prejudice to the rest. We ourselves could not exist but for bacteria. The most pregnant examples are those which come under the head of *symbiosis*. But since the life of every living organism on earth is more or less conditioned by the lives of all other organisms, it is quite admissible from a higher standpoint to regard all life on earth as a single great *symbiose*.

THERMOMETERS.

THEIR PRINCIPLE, CONSTRUCTION, AND INDICATIONS.

How frequently does one hear one person complaining of the excessive heat of a room, and another saying, "Do you think so? I do not find it uncomfortably warm." How often do they refer to a little instrument hung up perhaps on one of the walls, which tells them at once whether the heat of the room is greater than it should be or not. Yet few are aware of the physical laws which enable this little instrument to impart such valuable and trustworthy information to them, and fewer still know how it has been constructed. It is an everyday commonplace, thing, useful, cheap, and to them uninteresting. Attention may, perhaps, be drawn to the artistic carved frame in which it lies; but the workaday plain little thermometer comes in only for so much attention as is compelled by occasional discomfort or curiosity. Yet how essential is this little thing in one's daily life! By a little attention to this instrument we can contribute to the comforts of our life and prevent illness when well; and how much more is it necessary to have our little friend at hand when ill! Let us go into a hospital ward and see what use the instrument is put. The ward, with its lines of clean beds looks charming, and one feels neither too hot nor too cold. Perhaps there are several cases of typhoid fever in the ward: the little thermometer tells the house physician on his arrival many important facts about his cases, and every one well knows that when the senior physician comes round, one of his first questions in these cases will be, "What is the temperature?" One of the cases is worse, and must have a bath. The bath is ordered, in the language of the thermometer, to be of so many degrees. So you see that the little thermometer, like a good minister or doctor, does its work with equal truth and conscientiousness in whatever circumstances or conditions of life it may happen to be placed; therefore it behooves us all to have some intelligent idea, however slight, of the working ways of things like the thermometer, so useful, so liable to be overlooked. You may say, "Oh, but one can always tell whether a thing is hot or cold by feeling it!" True; but to what degree can you determine it? Let us give you an example. Supposing you took three basins: one having very hot water in it; the second, ice-water; and the third, moderately tepid water. If you placed your right hand in the cold water, and left hand in the hottest water, and after holding them there some time put both your hands in the tepid water, to the right hand it would feel warm, to your left hand it would feel cold. Which hand are you to believe? Assuredly there is a failing somewhere; and it lies in the fact that you cannot be sure of the previous temperature of your hand before feeling a body. Now the thermometer is not to be deceived in any way by sensation: it will always give the same record for the same degree of heat. And you must not confuse "degree" with "amount" of heat. If you had a large basin full of boiling water and took a cupful away, the cup would contain water of the same "degree" of heat; but there would be very much less heat in the cup as regards "amount." Inanimate objects are divided into "solids," "liquids," and "gases." The effects of heat on solids are twofold. Bodies are said to be made up of elementary particles called atoms, and roughly these atoms are in the closest proximity in solids, less in liquids, and least of all in gases. The first effect of the application of heat to a solid, such as iron, is to separate its atoms further from one another, and so make it larger. In other words, it expands. If heating be carried on to a greater degree, the solid becomes liquid, *i. e.*, adopts the shape of any vessel it may be in, having no shape of its own; and lastly, if the heating be carried on still further, the liquid becomes a gas. The *rationale* of the thermometer depends on the expansion of bodies exposed to the varying conditions of

heat. You know that when a thermometer endures a high temperature, the mercury rises in the tube and occupies more space. I dare say that many of you have noticed thermometers which had in them a reddish fluid instead of mercury. This is colored alcohol, and we shall consider the comparative merits of this kind of thermometer with the ordinary mercury one, later on. It occurred to scientific men that as certain things expanded under the influence of heat, the amount of expansion might be made to represent the degree of heat applied. Solids change in too slight a degree to lend themselves to purposes of measurement of fine gradations of temperature; gases, on the other hand, are too much affected by viarations of temperature to be useful for practical purposes; liquids, however, present the happy mean, and of these mercury is the liquid metal which expands most constantly equally for equal degrees of heat. A tube, having a fine bore known as a capillary bore, from the Latin *capillus*, a hair, is taken, and at one end of this a small bulb is made by means of a very hot flame; at the other end a funnel is made, into this funnel mercury is placed, and the bulb is heated. Some of the heated air rushes out through the mercury, and on cooling, some mercury is forced into the tube to take the place of the air which has escaped. This mercury finds its way into the bulb and is in its turn heated; it becomes volatile, and the whole tube being full of mercury and mercury vapor, all the air is driven out, and, on cooling, the tube fills with mercury from the funnel. The whole thing is again heated, and whilst hot the funnel is removed, and the upper end of the tube is sealed. On cooling, of course the mercury contracts and leaves above it a perfect vacuum. Our thermometer is now made, but we have to graduate it. It has been discovered that the temperature of melting ice is a constant one, that is to say, it is always the same. This temperature is known technically as the "freezing-point." The first thing to be done with our thermometer is to see at what level its freezing-point stands, *i. e.*, how high the mercury rises when the bulb of the thermometer is plunged into melting ice. This point is scratched on the glass with a diamond; but this fact is not enough to have ascertained. It has also been demonstrated that, at a certain pressure of the air, steam given off from boiling water is always of a constant temperature; it is necessary to obtain these conditions to ascertain what is called the "boiling" point of our thermometer. A special appartus is used, which is so devised that the whole of the thermometer, as well as the bulb, is enveloped in steam. Of course the mercury rises to a certain height, and this level also is recorded on the glass tube in the same way as the "freezing-point." Thus we have two fixed points from which to take a start in making our thermometer; but our own sensations are acute enough to distinguish between freeziug and boiling in the general acceptance of those terms, so we must subdivide the distance between the freezing and boiling points in our thermometer, and we may do so in various ways. Many of you may have noticed, on the thermometer at home, that the scale, as it is called, is printed on the frame of the thermometer, and the letter F. is placed at the top or bottom of the scale. This letter F. is distinctive: it is the first letter of the name of the chemist who invented the particular scale to which it is appended. His name was Fahrenheit. Fahrenheit found that he could artificially produce a much greater cold than that of melting ice, by means of a mixture of salt and snow. He therefore called the temperature of melting ice 32 deg., and that of snow and salt 0 deg., or zero. Boiling point on Fahrenreit's scale is 212 deg., so that between freezing-point and boiling-point on Fahrenheit's scale there are 180 degrees, or as it is written, 180 deg. This measurement of temperature is the one most in vogue in our own country; but amongst scientific men, and in most European countries, another scale is in use: this is the scale of Celsius, and is generally known as the "Centigrade" scale, from the following facts. Boiling-point and freezing-point are ascertained as already described, and freezing-point is called 0 deg., or zero, and boiling-point 100 deg.; and the distance between 0 deg. and 100 deg. is equally divided into a hundred parts, each of which is called a degree centigrade. Although these two scales of measurement are best known, there is another which you will see in those little ornamental thermometers which the German-Swiss make, and which is the scale used in Russia and Sweden; this is the scale of Reaumur. In this, as in the centigrade, or Celsius, scale, the freezing-point is 0 deg., but the distance from freezing to boiling-point is only divided into eighty equal parts, so that boiling-point Reaumur is 80 deg. The thermometers which are made with a red fluid inside instead of metallic mercury, are made with alcohol instead of mercury, and the alcohol is colored with cochineal or carmine, sometimes with Prussian blue. The method of making these thermometers is similar to that employed in those prepared with mercury, but they have a rather different character, which it is worth while for us to mention. Mercury at certain very low temperatures freezes, and therefore ceases to be of any service in recording low temperatures; alcohol has never been frozen yet, and therefore is of use in this way. Alcohol, however, boils at a lower temperature than water, and becomes a vapor; it cannot, therefore, be used for such high temperatures as mercury. The old-fashioned thermometers were made with a small spherical bulb; these, however, are not the best in shape, and the bulbs are made larger and thinner, thus giving a larger surface of exposure. Of such shape are the clinical thermometers used by physicians, which register from about 95 deg. Fahr. to 113 deg. Fahr. One often sees in a room the thermometer hung up against a wall. To do this is, strictly speaking, wrong; for if the wall communicates with the outside, and it be a northern wall, the temperature on that wall will be lower than the temperature in the middle of the room, where it is free of any object likely to affect its temperature. Similarly, a thermometer intended to take the temperature of the outer air is often placed outside a window, with the not sun shining on it. The thermometer, of course, registers much to high a temperature: it should be suspended in the open air, and in the shade.—*Demorest's Magazine.*

A DAY'S WORK.

WHAT IT CONSISTS OF IN EUROPEAN COUNTRIES.

A Turkish working-day lasts from sunrise to sunset, with certain intervals for refreshment and repose. In Montenegro the day-laborer begins work between five and six in the morning, knocks off at eight for half an hour, works on till noon, rests until two, and then labors until sunset. This is in summer. In winter he commences work at half past seven or eight, rests from twelve to one, and works uninterruptedly from that time to sunset. The rules respecting skilled labor are theoretically the same, but considerable laxity prevails in practice; in Servia the principle is individual convenience in every case. In Portugal from sunrise to sunset is the usual length of the working day. With field laborers and workmen in the building trades the summer working-day begins at half past four or five in the morning and ends at seven in the evening, two or three hours' rest being taken in the middle of the day. In the winter the hours are from half past seven to five, with a shorter interval of repose. In manufactories the rule is twelve hours in summer and ten in winter, with an hour and a half allowed for meals. Eleven hours is the average day's work in Belgium, but the brewers' men work from ten to seventeen hours; brickmakers sixteen; the cabinet-makers of Brussels and Ghent are often at work seventeen hours a day; tramway drivers are on duty from fifteen to seventeen hours, with an hour and a half at noon; railway guards sometimes know what it is to work nineteen and a half hours at a stretch, and in the mining districts women are often kept at truck loading or similar heavy labor for thirteen or fifteen hours. The normal work-day throughout Saxony is thirteen hours, with two hours' allowance for meal taking. In Baden the medium duration of labor is from ten to twelve hours, but in some cases it far exceeds this, often rising to fifteen hours in stoneware and china works and cotton mills, in saw-mills to seventeen hours; while the workers in the sugar refineries, where the shift system is in vogue, work twenty-four hours free; and in too many of the Baden factories Sunday work is the rule. In Russian industrial establishments the difference in the working hours is something extraordinary, varying from six to twenty. It is remarkable that these great divergences occur in the same branches of industry within the same inspector's district and among establishments whose produce realizes the same market price.—*Chicago Herald.*

GRAMMATICAL.— Teacher—"In the sentence, 'The sick boy loves his medicine,' what part of speech is loves?" Johnny—"It's a lie, mum."—*Medical World.*

CHEAP LIVING.—An official weekly journal in Germany calculates how an invalid workingman can live for 300 days in the year from the $75 allowed him by the Old Age and Invalid Insurance Fund: First breakfast, $11.25 annually; second breakfast, $7 50; dinner, $18.75; afternoon coffee, $7.50; supper, $15; rent, $11.25; clothing, $4.75.

ELECTRICAL ALARM.—Paris is laughing over a joke about an American inventor, who is said to have patented an electric corset that is to bring about the reign of morality at once. If one of these articles is pressed by a lover's arm it at once emits a shriek like the whistle of a railway engine, and the inventor claims that he has already married off three of his daughters, owing to the publicity thus thrust upon a backward lover.

BRUNETTE AND BLONDE. — A statistical inquiry undertaken by Dr. Beddoe has brought out the curious fact that in England a brunette has ten chances of being wedded to nine chances if she is a blonde, and the English women are gradually losing their fairness of skin and hair in darker types, simply because men persist in selecting the darker haired women for wives. The same thing is happening in Germany, France and Switzerland.

FRECKLES.—Halkins states that in carbolic acid we have a certain cure for freckles. The skin, first washed and dried, is stretched with two fingers of the left hand, and each freckle is carefully touched with a drop of pure carbolic acid, which is allowed to dry on the skin. Under its action the part becomes white and burns for a few minutes. In from eight to ten days the cauterized scale falls off, and the spot, at first a rose red, soon assumes its natural color.—*Edinburgh Medical Journal.*

ELECTRICITY FOR A FELON.—By electricity used as follows, a felon is destroyed by lightning speed: Use a good galvanic battery with ordinary power, then fill two glass dishes or cups with water, place the finger effected with the felon in one cup, in which you have placed the positive end of the electric wire; then place the next sound finger in the second glass cup, in which you have inserted the negative pole; continue passing the current from twenty to thirty minutes, and, if required, repeat this case in four or six hours. The pus that is exosmosed through the periosteum will appear as a pimple at the skin in a few days, and may require to be pricked with a needle.—*St. Louis Clinique.*

ELECTRICAL ENGINEERS.—The first class to receive the degree of Electrical Engineer (E. E.) from Columbia College was graduated June 10. Five post-graduate students received the degree. They had first obtained a thorough collegiate education, and then taken a two years' course entirely devoted to strictly electrical engineering work, without being interrupted or confused by other studies at the same time. Prof. Francis B. Crocker writes that this plan is found to give most excellent results, and it certainly seems a logical method of pursuing a course of study in so difficult a subject as electrical engineering.

BODILY SOLICITUDE.

THE PRIMARY PROBLEM FOR THE CONSIDERATION OF WOMEN.

While on every hand moral work, intellectual work, social work awaits every woman, young or old, whose life is so rich and full that it overflows into the world from the home, I am glad to see that there seems to be a growing appreciation of the importance of hygienic work as underlying all work of soul or brain. Whether for ourselves or for others, the first work toward enlarging and dignifying life is a work for the body—that body which is too often so unlike the temple in which God meant the human soul to dwell as the soul itself is unlike what he meant the dweller to be. All of us who have sought to inspire the very wretched classes with love of knowledge or with aspirations after better morals, have already found that our first battle would have to be in another field, that we needed to conquer outposts held by filth, by foul air, by bad food, by dark and dirty dwellings, before we could approach the citadel of the soul. We must send the plumber, and teach the religion of the scrubbing brush and the broom, and of light and air and food, and must drive out the multiform demons of dirt. Turning from the sufferers in the lower to those in the higher classes of life we find no less the hampering influence of disease. Could the women of the land, alive, as they are coming to be, to every mode of development and phase of progress, become thoroughly aroused to the fact that all progress along every line stops, and the backward course begins, both for the individual and the race, as soon as disease or feebleness of body sets in, they would have struck at last the lowest strata of reform, and we could hope for the future of the race. The foundation of all culture and of all development must be laid here, and women's hands are the ones to lay it. Build we ever so fair a structure on the basis of intelligence and goodness, and soon or late, if the hygienic conditions are wrong, it is undermined and falls. Without health the beautiful woman ceases to be beautiful, and of little avail are all our years of training and education if the possessor of their results is to pass her life a helpless victim of pain. There is a protest against ill in the very air. Disease is an unnatural and abnormal thing, and health resists it as long as it can. It takes the spring out of the steps and the ring out of the laugh, and hushes the voices of the little ones. And to a great extent it does this whether the invalid is patient and silent or not. The thing that is felt we influence by what we are not, by the much or the little we may say. Sickness is a blight which no woman should permit to come over her home if she can by any possibility cure it or keep it away. And women, we must admit, in all ages have been earnest seekers after and patrons of cures. And the result of all experience and observation convinces that if half the time and vitality spent in seeking a cure and in learning how to endure could have been turned toward prevention it would have given us another race. We need to become possessed by the truth that health is the great possession. Dr. Bartol opens his sermon on the mind cure by the statement that sickness and sin are twin born, and Emerson says that in varying health we have a searching preacher of self-control. How to secure good health, therefore, is one of the first problems for this generation of women. This is the demand their subject will make, of those they are crowning as of the hearth and the home. Give us bright, fresh, kindly hearted sisters, say the lads and the little brothers in the homes. Give us happy, healthy faces over our cradles, plead the babes who find their heaven in mother's eyes. Give us cheer and laughter, a little fun, say the fathers, turning wearily toward their firesides, at the end of a day of toil. Give us a bright word and a helping hand and your dainty touch on household ways, say the mothers who would give their lives any day to see their daughters well and strong and glad. Give us health is the cry from all the world to its women. Gives us girls with a physique that will spare us the morbid brooding of discontent, the hysterical tantrum, the nervous collapse, the look of gloom from the clear wells of their eyes. This is, as I have said, the problem of to-day. It is not our purpose now and here to suggest how best it can be solved. One little single hygienic law of sleep, of diet, of dress, of exercise, the first and simplest that you know, obeyed, and the work is begun. Knowing the next thing to do is not important until you have done the first thing you know.—*Harper's Bazaar.*

GOLD AND SILVER.

HOW THE ORES ARE ASSAYED.

The process of assaying silver ores is based upon the following considerations: Any compound of silver exposed to high heat in the presence of metallic lead or of oxide of lead and of a reducing agent gives up its silver in a metallic state, and in practice an alloy of lead and silver containing all the precious metal of the sample of ore used is obtained. The ore before being assayed is carefully sampled, so as to represent an exact average, as nearly as possible, of the mine, vein, or heap from which it is taken. It is next pounded in an iron mortar and the process continued until it is very finely pulverized. A sample is thus obtained which is given to the assayer. The first operation is to weigh out the powder. This must be done upon a fairly delicate balance. The quantity used for an assay depends upon the richness of the ore; it is very usual to base the weighing upon what is known as the assay ton, a weight of 29.166 grammes. One milligramme bears the same proportion to the assay ton that one troy ounce does to a ton of 2,000 pounds. In weighing, duplicate portions are weighed out representing from a fraction of one to several assay tons, according to the richness of the ore, and the operations are carried on in duplicate throughout. Each sample is mixed with from 8 to 16 parts of very pure, finely granulated lead, called "test lead," and a little borax glass. The fusion is very often done directly in a scorifier. These are shallow clay cups about 2 inches and 2¾ inches in width. The weighed portion of ore with the borax glass and lead being placed in one of these cups, the whole is introduced into a hot clay retort known as a muffle, which is heated in a muffle furnace. The heat is maintained at about 1,600 degrees. At this heat the lead in the scorifier melts and the ore floats on top of it, along with the melted borax glass. Gradually the ore disappears, its metallic constituents entering the lead and its earthy constituents forming with the borax glass a fusible slag. As a constant current of air is drawn through the muffle, the lead rapidly oxidizes and its oxide joins the slag, so that after a little while only a small circle of metallic lead appears in the center of the slag. This circle is gradually encroached upon, and eventually the slag covers over the button of metal, which at once sinks to the bottom and the scorifying is ended. After a little more heating the scorifier is withdrawn from the muffle and its melted charge is poured out into a hemispherical depression in an iron pan, in which it rapidly cools. When cold, a few blows of the hammer, the charge resting on an anvil, knocks the slag off. The spheroidal lead button is then pounded into a roughly rectangular shape, and is ready for cupellation. The cupels are shallow cups of bone ash, about 1½ in. in height, 2¼ in. in width and ⅜ in. in depth. They are made by hammering in a mould, a hammer and piston being used to drive the material down into the cavity of the mould and compact it. The cupel is first heated in a muffle and the rectangular button is placed in it. It at once melts and begins to oxidize. As fast as the oxide of lead is formed, it melts and is absorbed by the porous bone ash of the cupel, as water is absorbed by a sponge. This operation goes on until little more than the silver is left. Just at this point, as the last of the oxide of lead disappears, a sudden flash of rainbow colors passes across the surface of the button, the "brightening" indicating the expulsion of the last of the lead. The silver button is now allowed to cool, is removed by a pair of pincers from the cupel, and when cleaned and brushed free of the bone ash is weighed on an exceedingly sensitive balance. Each milligramme of weight represents an ounce or definite portion of an ounce per ton of ore, if assay tons have been used. The balance used for this weighing is one of the most sensitive made, and can indicate the twentieth of a milligramme readily. Should the ore contain gold, this is determined by "parting." The button is fused with one or two times its weight of pure silver. It is then rolled out into a thin sheet, and is treated with nitric acid. This dissolves the silver and leaves behind the gold and any platinum or similar metal which the ore may contain. This residue is weighed and is reported as gold. The weights used from the gramme upward, are usually made of brass, of the shape shown. From 500 milligrammes down to 10 milligrammes they are often made of platinum; the smaller weights are of aluminum, the fractions of a milligramme being made of wire bent so that the number of sides in each bent wires indicates the number of tenths of a milligramme which it represents. There are, of course, many refinements and modifications in the process which it is not necessary to summarize here. The assayer acquires by practice so good a knowledge of ores that he can properly proportion his charge from the appearance of the ore alone. A large number of assays can be kept going at once, the scorifiers and cupels being marked with numbers designating the sample for assaying which it is used.

DOMESTIC DIETETICS.

SPECIALLY PREPARED, FROM PRACTICAL TESTS, FOR THE LADY READERS OF THE "AMERICAN ANALYST."

SEASONABLE FOOD.

July.

MEAT.—Beef, lamb, mutton, ham, kidneys, liver, sausage, veal.

GAME AND POULTRY.—Pigeon, chicken, duck.

FISH.—Anchovy, bass, bluefish, blackfish, cod, eels, clams, flounder, haddock, halibut, herring, lobsters, mackerel, mussels, perch, porgie, prawn, salmon, shad, turtle, trout, sturgeon, whiting, weak-fish.

VEGETABLES. — Beans, cucumbers, carrots, cauliflower, egg-plant, lettuce, onions, parsley, parsnips, potatoes, shallots, spinach, turnips, radish, rhubarb, corn, beets.

FRUITS.—Cherries, strawberries, raspberries, huckleberries, melons, gooseberries, blaekberries, peaches, pears, tamarinds bananas, pineapples.

PRACTICAL RECIPES.

CARROT SOUP.—Scrape and cut into small pieces six fine large carrots. Cook them in two quarts stock until they may be mashed through a sieve. After the carrots have been mashed, return the mass to the soup and boil for a short time, season with salt, cayenne pepper and a little white sugar.

BREAD SAUCE FOR GAME AND FOWL. — Cut a French roll in slices and put it in a saucepan with a whole onion, a few whole peppers, a little salt and enough milk to cover them. Let it simmer gently until the bread soaks up the milk then add a little thick cream, or some milk and a lump of butter, take out the onion and rub the sauce through a sieve and serve.

MINT SAUCE.—Chop some nice fresh mint very fine, mix it with a very little water, some vinegar and sugar.

HORSERADISH SAUCE.—Chop up some parsley, a small young onion, a few capers and one or two anchovies; to these add a spoonful of horseradish scraped fine, a tablespoonful of oil, a little vinegar, pepper and salt.

BROWN COLORING FOR SOUPS AND SAUCES.—Put a quarter of a pound of fine sugar into an earthen pipkin and set it over the fire to melt. When melted it will be frothy, then put it farther from the fire until it is brown, stirring all the time. Add when brown a cup of red wine, a little salt, and lemon juice, a little ground cloves and mace, a grating of young onion and boil gently for ten minutes, pour into a basin till cold, then bottle for use.

RICE BALLS.—Cook two cups of rice until it is soft, then pack it into teacups that have been wet with cold water and set it on the ice to get very cold. When wanted for desert invert the cups into saucers and the rice will come out whole. Whip some cream until it is moderately thick, sweeten it and flavor with vanilla; pile it about the balls on the saucers and serve—or instead of cream serve custard flavored with vanilla with the rice.

LEMON CREAM CUSTARD.—Grate the peel and squeeze the juice of a large fresh lemon and add two and a half cups of water; pour into a porcelain kettle and set on the fire. Rub two tablespoonfuls of corn starch smooth in a little water, put it in a dish and pour slowly over it the heated lemon water, stirring all the time; add the beaten yolks of three eggs and set it back on the stove to thicken like custard; sweeten to taste. Remove from the fire, add the well-beaten whites of the eggs, pour into custard cups and let it get very cold before serving.

SAUCES AND DIGESTION.

Written for the AMERICAN ANALYST by W. E. S. Fales, U. S. Vice Consul, at Amoy, China.

Were man a mere animal, he could probably lead a very healthy and hearty life upon raw meat and fish, fruits, nuts and berries. Frequently he tries the same diet under the pretext of health-reform, but always comes to grief. Man civilized requires a varied regimen. He needs cooked food, and, what is too often neglected by well-meaning and otherwise intelligent persons, he requires the additional element of something which appeals to the palate on the one hand and facilitates digestion on the other. Only a high civilization produces a genuine sauce. To find the oldest sauces we need take only the oldest civilizations. Curry represents the Sanskrit, Soy the Chinese, Chutney the Sinhalese or the Persians, and Tabasco the Aztec. Nature seems to give us a hint at the origin of the use of these condiments. They grow in tropical or semi-tropical lands, seldom in temperate climes; the hotter the land, the more pungent and aromatic the spice. Black pepper from the Celebes and the small chili from equatorial South America are types in this regard. The reason is self-apparent. In the north man eats to keep warm; in the tropics no such necessity prevails. The blubber of the Esquimo, the tallow and train-oil of the Finn and Samoyed are fuel whose chief function is to heat the body. As you go southward the foods lose this quality by degrees and begin to show other attributes. Pork and fat beef, yellow corn and oatmeal become the staples. Then come the lands of the cereals and the heavy esculents. Last are the tropics, where fish, bird and beast are thin and where the fruits and vegetables are light and aqueous. At one extreme the principal purpose of food is sustaining animal warmth; locomotion, repair and relaxation are but secondary. At the other it is the very reverse. At one end life is one long struggle for sustenance; at the other nature supplies every want. On the other hand, the heat of the tropics produces lassitude and loss of appetite. Unless something intervened the human being would degenerate. Here nature steps in and to a varied food-supply adds any number of delicious and appetizing flowers, fruits, berries, leaves, barks and roots. The tropical man must have noticed this at a very early period and utilized it for both his pleasure and benefit. The Hakkas and Sanfats of Formosa, two savage tribes, use the soy-bean, the bay-leaf and the cinnamon bark in their cooking; the Malays the pepper, pumelo-leaf and allspice; the Kiche Indians, of Central America, the chili, and the Creeks and Seminoles the sassafras and wintergreen, which survive to-day in the famous gumbo filê of New Orleans. The development of civilization in these lands has increased the use of what may well be called food-accessories, and has also increased their variety and excellence. In India there are more than one hundred recognized kinds of curry; in southern Asia, one hundred and fifty of chutney, and in China at least fifty of soy, se-you or se-yow, as it is variously called. The principle underlying these preparations is one and the same. The palate and the nostrils are pleased, the appetite is excited and the digestion is strengthened. The Chinese go a step further, and in their soy endeavor to tone up the liver and to improve the condition of the bowels. In every case the evil effects of a high temperature are remedied and the body properly nourished. With invalids and convalescents the case is still stronger. The feeble organization requires food, but at the same time resents it. Here the condiment or sauce awakens appetite and strengthens assimilation. A drop of soy or a dash of curry converts what before was tasteless or repugnant into a delicious dish. The physicians and philosophers of the East have long appreciated these truths and preach and practice them universally. The physician goes so far as to be a special chef de cuisine, and in his treatment prescribes the soy and sauces which will conduce to his patient's rapid recovery. To-day the conditions of life in the West are practically the same as those in the East. Civilization, with its well-built houses, improved modes of heating not only homes, but offices, cars and boats, sensible clothing and food from every part of the earth, has made the daily existence of the citizen of Edinburgh, London and Paris, New York, Philadelphia and Chicago almost identical with that of Canton or Calcutta. The conditions are the same and the wants created by those conditions are necessarily the same. In the West, as in the East a good sauce is a physiologic necessity. The fact is already manifest from the innumerable army of preparations upon the market. Most of these are bad. They are carelessly and cheaply made from the poorest ingredients. They irritate the gastric system and, instead of doing good, do harm. The experience of every physician shows that they blunt the palate, injure digestion and frequently produce dyspepsia and other ills. The best are those based upon the Chinese soy. This, in essence, is a compound of the soy bean, an aromatic and delicious vegetable, salt, water and a touch of spice. In the East it replaces salt and is used upon nearly every dish. Upon soy as a basis, European manufacturers by the score have produced sauces of greater or less excellence. None are bad and some are admirable. The one where the soy idea is carried to perfection is Lea & Perrins' Worcestershire Sauce. The highest compliment that can be paid to it is the simple fact that it is the only article which displaces soy upon the tables of the mandarins and Chinese nobility. These are sybarites worthy of the days of Lucullus. What they use is the best the world affords. It is the last link in the chain of which the Amoy se-you, the Canton se-yow, the Indian Soy and the old English Soy of the first part of the century are the predecessors. It has a delicious flavor when used in small quantities, and is so rich and powerful that an excess will conceal faults in cooking without injury to the dish. Used as a condiment, or with water or with ice, it is a superb stomachic and appetizer. A Worcestershire Cocktail is a hundred times better than any alcoholic concoction, and is the only one a conscientious physician will recommend. It is more than an aid to the cook and does far more than merely please the palate and nostrils. It warms the stomach and increases the flow of both the gastric and the pancreatic juice. It acts benignantly so far as choleic acid is concerned and in this wise renders assimilation more rapid and complete. Above all, it does not weaken the digestive processes. A man can use it regularly a half century, and be benefitted to the very last. On the contrary, it frequently cures atonic dyspepsia, gastralgia and other assimilative ills. Taken all and all, it is the best, purest and finest sauce known to the modern world.

CITY NOISES.

HARMFUL EFFECTS OF THE CLANGING OF CHURCH BELLS.

The coming on of hot days, when invalids require open windows and persons in health are more or less irritable and nervous, has brought up again the question of the city bells. A correspondent quotes to us the remark of a lady which represented church bells as a nuisance that ought to be abated, and he feels shocked at such a sentiment. He appeals to us to visit our severest censure on this "sacrilegious" utterance, and asks us to give the history of church bells, and to say if their use is "dying out," as his friend asserts. The bell itself is older than written history. The earliest writings speak of the bell and of its various uses. Small silver and golden bells were attached to articles of raiment, giving a musical cadence to the steps of the wearer. The earliest Greek authors allude to the use of signal bells in camps and military stations. Even the ragman's bell is not a modern invention; according to Plutarch the trades people of his day rang their hand bells to attract buyers in the Athenian market. The Romans made constant use of bells in their homes, as we do now; and the hours of service in the public baths were announced by them. They were used on horses precisely as now, both to prevent accidents and to mark gala days and festive processions. The earliest record we can find of the use of bells in churches is in the account of Polydore Vergil, who says that Paulinus, Bishop of Nola, a city of Campania, was the originator of the custom about the year 400. For many years it was supposed that Pope Sabinianus, who used church bells in 604, was the first to sanction the custom; but later investigations proved their use in France as early as 550, and finally the tracing reached A. D. 400, back of which we find the bell employed for every other purpose, but not used to call worshippers to the church. The earlier church bells often contained large amounts of the precious metals, contributed by devout persons, that was put into the casting, and hence they had a very melodious sound, even the larger ones not being so offensive to the ear as those of more modern construction. They were consecrated, too, with solemn religious services, and this endeared them to the people. In the absence of clocks they gave to all within hearing the hour of service, but to the devout worshiper they had in their peal a call to devotion regarded with especial reverence. In England there was a common belief for many years that the use of bells was forbidden on houses of worship not in union with the Established Church. We had quite a controversy on this subject nearly forty years ago with a sturdy Enlishman of the John Bull type, who asserted first that a law of this character was still in force, and who, when driven from that position, then held that a statute forbidding the use of bells on chapels of dissenters and Roman Catholics had been on the books for many years, but might have been repealed. The trial which gave rise to the controversy came to an end in August, 1851,

and Lord Chief Justice Jervis, who gave the judgment described the prevailing impression as a "vulgar error," asserting that the common law gave "the right to use bells to churches of every denomination." In regard to the exercise of this right, however, he distinctly stated that no matter what was the name of the church, whether Protestant or Catholic, "the bells might undoubtedly be made use of in such a manner as to create a nuisance," and in this case they were liable to legal restraint. Public opinion is divided concerning the use of church bells in the city. It is urged that where time pieces are so abundant they are useless as indicating the hour of service. We do not think that this is quite true, as many will sit in full view of a clock without being reminded of the flight of time. To such the stroke of the bell is almost essential as a call to the house of worship. The burden of the complaints that have come to us rest on the ringing of bells at an early our in the morning, while most people have their night's sleep yet unfinished. In some neighborhoods there are sharp peals at or before six o'clock, and they are repeated as the successive hours of service are reached. We have no doubt that to many they are a real nuisance, the continuance of which can hardly be justified on any reasonable grounds The bells at later hours, beginning at ten and repeated for afternoon and evening service and for the session of the Sunday school, are by no means so annoying, since few people in good health are then in need of sleep. Even these later peals, however, will have a most painful effect on those who are languishing on beds of pain. We have sat by the side of the sick, to whom every stroke of the bell was a messenger of pain. The quickened pulse, the increased temperature of the body, the quivering of the excited nerves, all told of the injury to the patient, and frequently no alleviating medicines and no interval of rest would bring the invalid back to the recedent condition until long after the day with its church-going bells was over. It is a serious question whether, on the whole, the church bells do not inflict more harm than can be offset by the compensating good. At any rate, if not abolished, the annoyance might be abated by diminishing in a large degree the amount of the service. A few signal strokes might be borne with more patience than ten minutes of ringing succeeded by ten minutes of tolling, which is now the common infliction. The church bells are not the only offenders, but in the city most of the factories have substituted the steam whistle for the metallic peal. This is not a gain to the sufferers except that the shriek of the steam fiend is not as long continued as the ringing of the bell. We think these should be abated in all populous places. The owner of a factory has no right to send that fearful sound into a thousand homes for the sake of giving notice to the persons he employs that the hour has come for their assembling. We know many to whom these morning calls are a constant terror all the year round. They cannot accustom themselves to the repetition. Some are startled out of their morning sleep as by a sudden stroke and do not recover for hours, but most who dread the sound will waken before it is heard and lie in dread until it is over. The ordinary noises of the street, the outcries of itinerant vendors, the roll and jar of carts, the awful hand-organs, all make a confusion of sounds difficult for nervous people to bear; but the early bells and whistles ought to be suppressed at once and forever.—*Journal of Commerce.*

CORRECT DIAGNOSIS.—"Mornin', mum; is the docthor in?"

"I'm the doctor. What do you want?"

"Sure an' if yez wor the docthor ye'd know what waz the matther wid 'me widout the askin'."

"Yes, I can tell. You are afflicted with chronic impecuniosity and peripateticism, resulting from congenital lassitude, aggravated by persistent alcoholization."

"Great hivens! An' how long do yez give me to live?"

CASTING A STATUE.

THE CONSTRUCTION OF A STATUE IN A SINGLE PIECE OF METAL.

On June 25th Mr. J. Q. A. Ward's colossal bronze statue of the late Henry Ward Beecher was unveiled in front of the City Hall in Brooklyn. The following description of the process of its construction is condensed from the *Scientific American.* The statue is remarkable as being cast practically in a single piece, the head being of one piece with the body. Originally metallic statues were made in small pieces, and were united by rivets or soldering. Some were cast solid. The present practice is to cast them hollow, and as thin as possible. This secures rapid cooling and tends to prevent any separation from the constituents of the alloy. It also economizes in metal. The first step in making a statue is the production of the plaster model. This is supplied by the artist, and it comes from his studio of the exact size required for the final statue. The original studies in the case of colossal statues such as the present may be very small, but before the artist is done with his work, the full sized model is produced. In the present case the statue was to be about nine feet high. The area of the flask in which the mould was to be made was seven feet four inches wide by thirteen feet six inches long. The model was established upon the lower section of the flask and the work of building up the mould began. The sand used is mined in France. It possesses to a high degree the property of consolidating, yet is very porous. A famous bed of the material is at Fontenay-aux-Roses, about 16 miles from Paris. This is compacted by wooden mallets and hand rammers of different shapes. As the artist produces his statue without any reference to its capacity for "drawing" from the mould, the bronze founder has to adopt his work to the most exacting conditions of undercutting and complicated outlines. The mould is, therefore, built up in very numerous sections, some of them extremely small. An exact count was not kept, but in the present statue between one thousand and fifteen hundred pieces were used in the mould. The statue is eventually completely embedded in clay. The mould has now to be opened up, the edifice of over a thousand sections is carefully taken down and the model is lifted from its resting place upon the lowest flask section. The mould is next rebuilt, the inner surface receiving a coating of foundry facing, and the interior is rammed full of clay to form the core. This core need not be solid. Some spaces may be left in it for the gases to collect in. Thus the mould is a second time complete and intact, but is filled with a clay figure instead of a plaster one. The mould is a second time dismantled and the core taken in hand. From its entire surface a layer of clay is removed, to average, as nearly as possible, one quarter of an inch in depth. This delicate operation provides the space for the metal to occupy in the casting process. This core thus reduced in size is replaced upon the flask and is properly supported. The mould is a second time built up, surrounding in this case the reduced core. A number of channels or gates are worked in the mould to allow the metal to run through to different parts of the figure. These resemble somewhat the trunk and branches of a tree. They start from a comparatively large section near the pouring reservoir, and fork and diminish repeatedly, reaching the space between core and mould in many places. When all is perfectly dry, and the flask filled with sand so as to hold all the pieces in place, the operation of casting is proceeded with. In the present case seventeen weeks were required for the moulding. The process of casting a bronze statue is executed either by surface or bottom casting. In the latter method a reservoir is arranged over the gates, which reservoir is large enough to hold all or a large portion of the metal. It has holes in its bottom corresponding exactly to the gates in the mould. These holes are plugged. The metal is poured into the reservoir, and by withdrawing the plugs the metal runs down into the space in the mould. The Beecher statue was cast by surface pouring. The metal held in crucibles was poured directly into the gates. This enabled a constant watch to be kept upon its fluidity and general nature as far as shown in its fusion. A man, as the metal was poured, kept scraping back all scoria, slag, and oxide from its surface. The adoption of one or the other system of pouring the metal rests, as a matter of preference, with the individual founder. For the Beecher statue 7,400 pounds of metal were melted repeatedly. The fourth fusion was the one used. Eleven minutes were occupied in the casting, and the the finished statue weighed 3,600 pounds. The rest of the metal represented the contents of the gates, waste, etc. The alloy was composed of copper 90 parts, tin 10 parts, zinc 3 parts.

ADULTERATED ESSENCES.

OIL OF LEMON MADE OF TURPENTINE.

There is reason to believe that a great many cheap and nasty essences are finding their way into this country this season. We suppose that the keen competition which in many places exists amongst mineral water makers, together with an unfortunate tendency in certain quarters to keep up the old-fashioned profits at the expense of quality, has created a demand for cheap essences. Now there is cheapness and cheapness; but the kind of cheapness which we would warn our subscribers against is that which is produced either by dilution or by the addition of foreign substances, which may or may not be harmful, but which certainly have no business to be employed. It may come as a surprise to some that essential oil of lemon is being adulterated with oil of turpentine! It has been met with in our Analytical Department very skilfully blended with the genuine oil of lemon. In general appearance the oil of lemon is scarcely affected by the addition of this adulterant, but an educated palate will generally detect "something wrong" without being able to suggest what that something is. Sophistication may be *suspected* by the general appearance, flavor, etc., of the essence if the buyer is experienced; but if there is any doubt it would be advisable before laying in large

ORIGINAL. No. 54.

Fruit Pinwheels.

BY MARIA PARLOA.

Mix together and rub through a sieve one pint of flour, one tablespoonful of sugar, half a teaspoonful of salt and two teaspoonfuls of Cleveland's baking powder. Into this mixture rub two generous tablespoonfuls of butter. Wet with a scant half-pint of milk. Sprinkle the board with flour, and, putting the dough upon it, roll down to a large square about half an inch thick. Spread a heaping tablespoonful of soft butter on this and then spread with a cupful of sugar and a cupful of currants. Grate a little nutmeg over all, and roll up like a jelly roll—or pinwheel style. Cut in slices about three-quarters of an inch thick and lay in well buttered pans. Do not let the slices touch each other. Bake in a very quick oven for about twelve minutes. These are nice for luncheon or tea.—(Copyright, 1891, by Cleveland Baking Powder Co.)

Use only Cleveland's baking powder, the proportions are made for that.

With Cleveland's Baking Powder cake keeps fresh; breads are fine grained; biscuit light and flaky. Try a can, Cleveland's.

stocks, and before risking the character of one's mineral water by using a raw material of doubtful purity, to submit the essence to chemical examination.—*London Mineral Water Trade Review.*

COLOR RETURNING.—In Saratoga, N. Y., a singular freak of nature has manifested itself. Mrs. Mary Francis, when she was young and also while she was in the prime of life, had very black eyes and a beautiful head of very black hair. She is about 70 years old now, in good health, and a rich widow. When she was about 50 her hair began to turn white, and in a few years the whole of it was as white as snow, and so remained until about a year ago, when it began to turn black again, and has now, without the use of any artificial means and purely as a freak of nature, almost wholly returned to its original color, and is as long and silky as when she was a young woman.

RUSSIAN COTTON.—Prince Golitzen, who has recently returned from a tour through the cotton regions of Central Asia, represents the cotton cultivation there as an industry of rapidly growing importance, and that the revenue from it is at the rate of $87.50 per acre. The establishment of ginneries is referred to as one of the peculiar features of the greatly increased cultivation of cotton, the tendency being that it will be carried to an excess, because of the present large profits derived therefrom. There is a report on the cotton industry in Asia in the possession of the State Department, Washington, from the Consulate at St. Petersburg.

25 CTS PISO'S CURE FOR CURES WHERE ALL ELSE FAILS. Best Cough Syrup. Tastes good. Use in time. Sold by druggists. CONSUMPTION 25 CTS.

Armour's

Extract of BEEF.

The best and most economical "Stock" for Soups, Etc.

One pound equals forty-five pounds of prime lean Beef.

Send to us for our book of receipts, showing use of ARMOUR'S EXTRACT in Soups and Sauces.

Give Ear

To the plain facts about *Pearline*, and then give *Pearline* a chance to prove them, by giving it a fair trial. Nothing else will give the same result. It washes safely, as well as surely; it cleans carefully, as well as easily. It is as cheap as soap and better. Anything that can be washed, can be washed best with *Pearline*. It lightens labor and does lightning work. As nearly as we can figure, about eight millions of women use it. Do you? You will sooner or later.

Don't Listen

To peddlers or unscrupulous grocers who offer imitations of Pearline, and say, "it is just as good as," or "the same as" Pearline. IT'S FALSE.—Pearline has no equal and is never peddled.

237 JAMES PYLE, New York.

BUSINESS NOTES.

FRUIT PRESERVES.

In nearly all the reports of State Commissioners published during the last year was contained a more or less severe criticism of the fruit preserves found in the market. Yet not in a single instance was there any mention of the goods bearing the label of Gordon & Dilworth, New York. The reason for this is obvious. This house only puts up first-class goods from the best materials and has but one brand, the best. Nothing too good for our trade, is their motto, and this is strictly lived up to by every one connected with the establishment from the proprietors, who all work in the factory, down to the humblest and youngest employee. It would be well if there were more such houses.

HARTSHORN'S SPRING SHADE ROLLERS.

Spring shade rollers are so well known now that everyone uses them and it is only a question as to whose make to buy. This is easily answered. Stewart Hartshorn is the originator and was the man who first created a demand for what is now an indispensable household article. Imitators cannot use his interior construction as his patents covers these, bnt must be content with imitating the outward appearance resulting in imperfect goods whose only claim is apparent cheapness, while in reality they are dear at any price becanse they are worthless. With Mr. Hartshorn the rule is that goods must be perfect, and with forty years experience, the best workman, well-lighted brick factories, complete machinery and ample capital, he is enabled to turn out satisfactory goods, cheaper than any other house. Improvements in construction are constantly being made, and if they stand the test of wear are added to every roller turned out. The greatest care is taken both in material and workmanship, regardless of cost, to obtain the best results. These rollers may now be found not only in every part of the United States but all over the world. The lesson is, be sure to get Hartshorn's spring rollers.

TAKE HEED!—Are the large American cities ceasing to be American? Last year, for instance, in Chicage there were 172,756 votes cast at the election, of which 88,509 were cast by naturalized citizens. This naturalized vote was divided as follows: Germans 33,002, Irish 20,253, Swedish 6,864, English 5,620, Canadian 4,402, Bohemian 3,447, Norwegian 2,998, Polish 2,774, Scotch 1,810, Austrian 1,507, Danish 1,267, Russian 960, Hollanders 911, Italian 686, Swiss 628, French 547, Hungarian 169, other foreigners 402.

WHERE HE FITTED.—"I don't know what to do with the boy," said the discouraged father. "He is industrious enough, but he isn't truthful. He'd rather lie than go fishing. I never believe a word he says unless I know it to be true beforehand." "I need a young man," said the guest, the proprietor of a baking powder factory, eagerly, "in my advertising department.—*Chicago Tribune.*

AN OPEN POINT.—It seems to be a mooted question whether or not a man can be a successful business man and a christian. There is no reason why a man cannot be both. The trouble lies in the fact that most men make a business of their Christianity. They look upon it as so much stock in trade. Christianity don't pay when you try to make it pay. Make a note of it.—*Grocers' Monthly Review.*

RELATIVE VALUES.—The value of skilled labor is most strikingly shown by the following: A bar of aluminum that is worth only $5 in its natural state is worth $12 when it is made into household utensils; after it has gone through the different processes by which it is made into jewelry, its value is increased into $150.00. Made into match cases, it would be worth $300; put into the balance wheel springs for watches, $250,000.

FOOT-BALL CASUALTIES.—The last foot-ball season in England has been noted for the casualties recorded. Among the injuries noted in the Lancet, which ended fatally are, asphyxia, caused by paralysis of the muscles of respiration, acute peritonitis, injury to the brain, rupture of the intestine, rupture of the right kidney, and abdominal injuries. Is it not time that this game should be so modified as to relieve it of the unnecessary dangers now attending it?

BUSINESS WOMEN'S DRESS.—On May 31, the Executive Board of the Women's National Council, in Indianapolis, appointed a committee to prepare a symposium on dress, to be published under the auspices of the National Council in one of the popular magazines during the coming year and report to the conference of the Executive Board of the Council of May, 1892, its idea of a business dress for women, accompanied by a model of the same. The Corresponding Secretary was authorized to correspond with Marion Harland about a stone to be placed in the monument to Mary Washington and to collect the money for the same.

BINDER TWINE.—The binder twine is used by the wheat-growers all through the Western country to bind up the wheat, and from sixty-five thousand to seventy-five thousand tons are used every year in this way. The binding is done by machinery, and it is said that McCormick, of Chicago; the Walter Wood Company, of Hoosac Falls, and other concerns turn out 200,000 binders every year. Wire was once used for binding, but pieces would get in between the mill stones and the millers naturally opposed its further use and opposed it successfully. Our wheat crops this year are so large that many thousand more tons of binder twine will be used for binding wheat than ever before.

WATCHES.

EVERY one wants a watch, and naturally a good watch that keeps accurate time, presents a handsome appearance, and is inexpensive. If such a watch can be found of American manufacture, it is an additional appeal to our patriotism. Just such a watch as this ideal THE ANALYST PUBLISHING COMPANY is enabled to offer as a Premium to its readers. Having some large advertising contracts we have been enabled to procure the movements of the manufacture of the best known American watch factories, namely, the Waltham, Elgin, Hampden and Illinois Watch Companies. These movements are adapted for both ladies' and gentlemen's watches, and are warranted by the makers. These movements have seven jewels, patent lever movement, chronometer balance, patent safety pinion, sunk hard-enameled dial, straight line visible palette, stem winders, hand set; in fact, contain all the latest improvements and can be readily cleaned or repaired by any ordinary good watchmaker. They can be regulated to run as close as any movement.

It is needless to say that to case these movements in solid gold cases would make them too expensive, yet they are cased in what are known as gold filled or stiffened "Ladd" cases, and are warranted to be 14 karat gold, made from two sheets of 14 karat gold overlaying fine composition metal, with regular jointed caps, covers and bezels, and to wear at least five years. They are not plated, nor rolled gold, but actual 14 karat gold cases, thin of course, but stiffened and strengthened by being filled with this fine composition metal. They are finished in the same manner, engine turned and engraved as solid gold watches, and wear and look just the same. No one but an expert can tell them from a solid gold watch. These watches are made both open face and hunting case style, in gentlemen's or ladies' sizes. For gentlemen we recommend plain engine-turned cases; for ladies, a handsomely engraved case.

How to Obtain One of these Watches.

These watches are not to be purchased from us at any price. Send us a club of 25 subscribers to the AMERICAN ANALYST, and $25, the regular subscription price, and one of these watches (your choice of style and size) will be immediately forwarded, post-paid and registered, to your address. You need not wait until you have your 25 subscribers all together, but forward them as you get them and they will be credited to you, and when the number is complete the watch will be sent. A subscription for two or three years will be counted as two or three subscribers.

As these watches are retailed by jewelers at not less than $25, it will be seen that we are offering a real premium with the sole object of increasing our circulation, and that by taking advantage of our offer any one can obtain a good, reliable and handsome watch without cost. As the number of these watches at this price is limited, it is advisable to take steps at once to procure a bargain.

THE ANALYST PUBLISHING CO., 19 PARK PLACE, NEW YORK.

BICYCLES

GIVEN AWAY TO BOYS AND GIRLS!

AN OPPORTUNITY OPEN TO ALL.

The Analyst Publishing Company being desirous of largely increasing their subscription list, will furnish every one with a beautiful Safety Bicycle, ABSOLUTELY FREE, in return for a few hours' canvassing.

To every boy and girl who secures 75 subscribers for the American Analyst at $75, we will give a splendid

$40.00 NONPAREIL SAFETY BICYCLE.

These bicycles are adapted in size to boys, but are strong enough to carry a man. A boy's bicycle should be a strong one. They are manufactured by the OVERMAN WHEEL CO., the makers of the celebrated VICTOR Bicycle, and have the full guarantee of the makers.

The following is a brief description of the NONPAREIL SAFETY; 26-inch wheels; ball bearing all around, including pedals; solid crescent rims; double tangent spokes; three-fourths inch tires; cranks, three throw, $4\frac{1}{4}$ to $5\frac{3}{8}$ inches; guards to both wheels; tool-bag, oiler and wrench. Finished in bright enamel, all exposed metal heavy nickel-plate on copper.

In selecting these machines as a premium, we have disregarded cheapness and selected a Bicycle which is serviceable, and the makers of which have an established reputation for building the best Bicycle that money, machinery and brains can produce. We are actually furnishing the Bicycles and Papers at less than cost, but hope by stimulating active and successful canvassing, and thus enlarging our subscription lists, to make an eventual profit. We positively guarantee these bicycles to be just as here represented. They will be shipped by express f. o. b. in New York.

Subscription orders must be made out plainly and legibly, and sent as fast as secured, addressed to

THE ANALYST PUBLISHING CO., 19 Park Place, New York.

TABASCO PEPPER SAUCE,

OR LIQUID PEPPER.

Is simply the Pulp of the Ripe Pepper Extracted by Pressure.

The seed of this Pepper was obtained from Central America, and by careful cultivation in Louisiana for many years has been so improved in strength, flavor and aroma, as to have become a new variety of Red Pepper, superior to all others. The pulp is so handled as to retain all the flavor, strength, aroma and color of the ripe fruit, and to keep unimpaired in any climate. It excites the appetite, promotes digestion, and is pronounced by connoisseurs to be the finest condiment in the world. For medicinal purposes it recommends itself by its purity, strength and diffusible form.

Manufactured by E. McILHENNY'S SON,

NEW IBERIA, LA.

For Sale by all Wholesale Grocers.

WOMANKIND.

INSTRUCTIONS TO SUBSCRIBERS.

The **Names of all Subscribers** are registered as soon as received, and paper is always promptly forwarded.

Postage.—The postage to all parts of the United States and Canada is paid by the publisher.

Remittances of small sums may be made with comparative safety in ordinary letters. Sums of one dollar or more must be sent by registered letter or P. O. money order, otherwise we cannot be responsible for same. Silver must not be sent in a letter.

Postage Stamps will be received for the fractional part of a dollar, and in any amount when it is impossible for patrons to procure bills, but you must send one or two-cent stamps only.

SUBSCRIPTIONS.—The AMERICAN ANALYST will be sent one year to any subscriber for ONE DOLLAR. New subscriptions can begin at any time.

We Stop the Paper at the expiration of the time paid for unless a renewal of subscription is received. Those whose subscriptions have expired must not expect to continue to receive the paper unless they send the money to pay for it.

Change of Address.—Subscribers wishing their addresses changed must invariably give their former as well as new address.

Missing Numbers.—It occasionally happens that numbers of our paper sent to subscribers are lost or stolen in the mails. In case you do not receive any number when due, write us a postal card and we will cheerfully forward a duplicate of the missing number.

Most Important of All.—In every letter that you write us, never fail to give your full address, plainly written—name, post-office, County and State.

Address all letters to

THE ANALYST PUBLISHING CO.,

GRAND PREMIUM OFFER!

A SET OF THE

WORKS OF CHARLES DICKENS,

In Twelve Large Volumes,

Which we Offer with a Year's Subscription to this Paper for a Trifle More than Our Regular Subscription Price.

CHARLES DICKENS.

Wishing to largely increase the circulation of this paper during the next six months, we have made arrangements with a New York publishing house whereby we are enabled to offer as a premium to our subscribers a **Set of the Works of Charles Dickens, in Twelve Large and Handsome Volumes,** with a year's subscription to this paper, for a trifle more than our regular subscription price. Our great offer to subscribers eclipses any ever heretofore made. Charles Dickens was the greatest novelist who ever lived. No author before or since his time has won the fame that he achieved, and his works are even more popular to-day than during his lifetime. They abound in wit, humor, pathos, masterly delineation of character, vivid descriptions of places and incidents, thrilling and skillfully wrought plots. Each book is intensely interesting. No home should be without a set of these great and remarkable works. Not to have read them is to be far behind the age in which we live. The set of Dickens' works which we offer as a premium to our subscribers is handsomely printed from entirely new plates, with new type. The twelve volumes contain the following world-famous works, each one of which is published *complete, unchanged, and absolutely unabridged:*

DAVID COPPERFIELD,
MARTIN CHUZZLEWIT,
NICHOLAS NICKELBY,
DOMBEY AND SON,
BLEAK HOUSE,
LITTLE DORRIT,
OUR MUTUAL FRIEND,
PICKWICK PAPERS,
BARNABY RUDGE AND CHRISTMAS STORIES,
OLIVER TWIST AND GREAT EXPECTATIONS,
THE OLD CURIOSITY SHOP AND THE UNCOMMERCIAL TRAVELER,
A TALE OF TWO CITIES, HARD TIMES AND THE MYSTERY OF EDWIN DROOD.

The above are without question the most famous novels that were ever written. For a quarter of a century they have been celebrated in every nook and corner of the civilized world. Yet there are thousands of homes in America not yet supplied with a set of Dickens, the usual high cost of the books preventing people in moderate circumstances from enjoying this luxury. But now, owing to the use of modern improved printing, folding and stitching machinery, the extremely low price of white paper, and the great competition in the book trade, we are enabled to offer to our subscribers and readers a set of Dickens' works at a price which all can afford to pay. Every home in the land may now be supplied with a set of the great author's works.

GLENN'S SULPHUR SOAP.

Glenn's Sulphur Soap is the **Original** and **Best** combination of its kind, and the one now generally in use. For sale by **All Druggists.**

BEWARE OF COUNTERFEITS.

Wholesale Depot,

C. N. CRITTENTON,
115 FULTON STREET,
NEW YORK.

Be progressive and keep abreast of the times. Avoid dyspepsia by using **Lard Compound** and **Cottolene,** a substitute for lard.

The highest medical authorities pronounce them healthful; and expert cooks commend them.

Our **Clairette** brand of cotton oil soap is the purest and best laundry soap in the market; as pleasant to the hands as genuine castile.

N. K. FAIRBANK & CO.,
CHICAGO AND ST. LOUIS.

OUR GREAT OFFER

TO SUBSCRIBERS

TO THE

AMERICAN ANALYST.

We will send the **ENTIRE SET OF DICKENS' WORKS,** *in* **TWELVE VOLUMES,** *as here described, all postage prepaid by ourselves, also* **THE AMERICAN ANALYST** *for* **ONE YEAR,** *upon receipt of* **$1.50,** *which is only* **50** *cents more than the regular subscription price of this paper.* Our readers, therefore, practically get a set of Dickens' works in twelve volumes for only **50** cents. This is the grandest premium ever offered. Up to this time a set of Dickens' works has usually been $10.00 or more. Tell all your friends that they can get a set of Dickens' works in twelve volumes, with a year's subscription to **THE AMERICAN ANALYST** for only **$1.50.** Subscribe now and get this great premium. If your subscription has not yet expired, it will make no difference, for it will be extended one year from date of expiration. We will also give a set of Dickens', as above, free and post-paid, to any one sending us a club of three yearly subscribers.

NEW PROBABILITIES.

On the first of July, as our readers are aware, the Government Weather Bureau passed out of the hands of the Army Signal Service, and became an adjunct of the civil service under the Department of Agriculture, in charge of Prof. Mark W. Harrington, professor of astronomy at Ann Arbor. There is still a good deal of speculation, in army circles especially, as to the wisdom of this change. So long as the Bureau was attached to the Signal Corps, there was at least the advantage of military discipline, which extended even over the civil assistants ; and this was no small consideration in view of the accuracy with which every observation has to be taken and timed and recorded. Now that the "probabilities" and "indications" have become so familiar a factor in the day-life and thought of the people, it seems odd to note the comparative recency of their origin. Since the early forties a good deal of interest has been taken in barometric, thermometric, and rain-gauge observations, but these were at first irregular and unsystematic. The instruments used even by professional observers were rarely perfect, and, there being no uniformity of plan among the several observers, no valuable scientific results were obtained. Lieut. Maury, U. S. N., is credited with being the first to recommend international co-operation, and in 1852 Sir John Burgoyne, British Inspector-General of Fortifications, established a system of meteorological observations on land, to be conducted by the Royal Engineers. A correspondence took place between the British Government and ours, with a view to having all the land and sea observations in either country follow certain uniform lines, so that comparisons between them would be of some real value. The upshot was that all the leading maritime nations were invited to send representatives to a conference held at Brussels the next year. The conference decided that it would be impracticable to establish uniformity of scales and instruments, but that the most that could be done would be to secure accuracy with each of the different kinds. The impulse given to popular interest in the subject by all this discussion, however, resulted in the creation of a meteorological department by the English Board of Trade, which has been followed by the gradual development of weather bureaus in all the different countries.

AN ALBANY KICKER.

We trust that we shall not lay ourselves open to further critical demolishment at the hands of our erudite contemporary, the *New England Grocer*, by quoting the following editorial from the *Merchants' Mail*, of Albany, N. Y., regarding the "Pure Food" movement :

Some manufacturers in New York City have gotten together and formed an association to be known as the "Food Manufacturers' Association of the United States." The object sought to be gained is to manufacture pure and wholesome food. Quite a praiseworthy object, indeed. But every one knows that there is a great deal of bosh and nonsense about this whole business. The dairy commissioners' reports of the different States show the number of food articles that are adulterated, and many manufacturers who would go in such an organization are the ones who put out the worst kind of goods. How many of the present members of this new organization would be in favor of a law requiring the ingredients to be printed upon the label? Suggest that once, and you would immediately hear a howl from these manufacturers that such a law would compel the making public of the *formula*. Nothing of the sort. Now, this association, in connection with the Grocers' Union of New York, propose giving an exhibition, which we take to mean that nothing shall be admitted unless the same is absolutely pure. In such a case there will be a daisy old exhibit. How does the manufacturer get rid of his adulterated and poor goods? Through the retailers; and easily one-half the grocers of this State stand ready to take such goods and palm them off on the unsuspecting and innocent public.

PROTECTIVE ABSTINENCE.

According to a writer in the *Nation* the agency of railroad companies in promoting temperance is not generally appreciated. They employ in this country 689,912 persons, not counting those who mine the coal and iron, make the rails or locomotives, or build the cars and carriages used by the road. The freight and passenger traffic of the country is practically controlled by 600 of these corporations, and of these 600 no fewer than 375 prohibit the use of intoxicating liquors by their employes, among the number being most of the largest companies. The Brotherhood of Locomotive Engineers uses its influence in the same direction. "Whenever a member of the order is known to be dissipated," says Mr. Arthur, long the head of the organization, "we not only expel or suspend him, but notify his employers," and during the last year 375 members were expelled for this cause. This is only one illustration of the way in which practical business considerations are operating to promote the spread of temperance. It is purely a matter of business with the railroad companies. They simply cannot afford to employ a man who is liable any day to get drunk and precipitate some terrible disaster The average man thus comes to see that it is "money in his pocket," in more senses than one, if he keeps out of the saloon ; and the moral is not lost upon him."

COFFEE FRAUDS IN FRANCE.

We read in our French exchanges that a proposed coffee adulteration bill is exciting much interest among the proprietors of cafés in that nation. It seems to have been supposed, writes a correspondent, "that if coffee is bought in the grain, and ground up at home, the consumer is sure of having it pure. This, it seems, is a mistake. The consumer is not sure of having his coffee pure, even when he buys it in the grain. The reason of this is that there is a great deal of artificial coffee manufactured, and manufactured so that, so far as appearance is concerned, it is impossible to tell it from real coffee. There is, indeed, some slight difference about the little crack in the grain, but this is difficult to recognize except by an expert. But if the grain be burst by pressing it between the fingers, there will be a small quantity of a blackish-looking powder, and if this is tasted it will be found to be slightly bitter, but otherwise very insipid. It would be impossible to make coffee with this material, for the blackish-looking powder is nothing but flour and sulphate of iron. This substitute could not be sold for coffee by itself, of course ; but when it is mixed with real coffee it is very easily passed for the pure article. Of course, the mixture makes very bad coffee, and is in many cases injurious to the health." With a view to altering this state of things, a Delegate has framed a bill to bring before the Chamber, which forbids the manufacture, the exposition for sale, the importation or ex-

portation of any product which by its form, its color, and its aspect generally, is susceptible of being taken for, or bought as, coffee in grain, either green or roasted. Article II. of the new bill decrees that the offenders against Article I. will be liable to fines of from 50f. to 3,000f., and they will be considered as having acted in knowledge of the fraud if they do not declare the names of the seller or the forwarder. Article III. says whosoever shall sell, or try to sell, as real coffee, green or roasted, any product which is not coffee, will be punished by a term of imprisonment of three months at the least, and of one year at the most, together with a fine of 50f. at the least. Article IV. decrees that the aforesaid fines and penalties shall be doubled if the adulteration has been found to be hurtful to the health, or if it has been fraudulently mixed with real coffee. All these penalties to act independently of the Articles in the Penal Code which deal with the various kinds of frauds. In a manufactory of this artificial coffee as many as 40 or 50 kilogrammes are turned out in a day, that is, between 80 and 100 pounds. The materials of which these goods are composed are about 15 kilos. chicory, 36 kilos. flour, and 500 grammes of sulphate of iron. The bright appearance is given to the grain by means of a special oil.

COMELY AND PLUMP.

ADVICE TO WOMEN SEEKING TO CULTIVATE ADIPOSE.

(*Celia Logan in the N. Y. Press.*)

In youth—"the season made for joy," as Sheridan phrases it—a girl should be plump enough to be pleasing to the eye. Her jaw and cheek bones should have sufficient flesh upon them to give a soft, rounded contour to her face. Her neck, like a column, should have every chink covered and rest upon firm shoulders, well filled in to hide the clavicles. The chest should rise into a gently swelling bust and thence slope evenly downward to the round, supple waist. From the shapely arm no sharp elbow joint should protrude, but should taper down to a bone hidden wrist, supporting a small dimpled hand, with fingers prettily curved. Alas! not to every daughter of Eve is given the exact proportion of adipose tissue indispensable to a faultless form. Many of our girls are too thin, and, knowing it, resort to various specious artifices of dress to conceal their skinniness, and succeed fairly well as far as the body is concerned, but there are points of the human frame which defy art to soften or change them. When art fails them our women, enlightened and progressive, call upon science to aid them, and I, an humble exponent of one small, but not unimportant branch of it, have been asked if, knowing how to teach the fat girl to become slender, I cannot instruct the too slim girl how to coax adipose tissue enough upon her bones to meet the requirements of beauty. Unhesitatingly I reply that it can be done, always provided that the person is healthy, that the thinness arises from no disease such as atrophy of the tissues of the body, a malady which mainly supplies museums with their "living skeletons." This wasting disease is caused by want of healthy digestion and assimilation, which gradually deranges the blood glands so that they cease to form blood in quantity sufficient to nourish the body. Corpulence and fattening always originate in the way people live and eat. This was proved by a Dr. Chambers, surgeon to the Queen of England. He delivered a series of lectures upon corpulence in 1850, and until 1863, when Banting's "Letter" appeared, Chambers was the highest British authority upon this subject. He related several experiments which had been made with a view to ascertaining the exact relation of diet to obesity, and cited the case of a thin young girl who was fed upon chestnuts and allowed to drink a great deal of champagne. In a short time she became enormously fat, but returned to her natural shape when permitted to resume a rational diet. Liebig was of the opinion, based upon his experiments, that fat is formed directly from the starches and sugar eaten, and upon his authority it is stated that one's weight can be increased at the rate of a pound a week merely by eating five ounces of sugar daily. This does not mean by using it as a sweetening to coffee or tea, but by eating it solid. More recent investigations than Liebig's show clearly that the albumen (the floury part in corn, wheat and like grains, the fleshy part of the cocoanut, and so on) is the principal source of the fat stored in the body. This albumen, after it has reached the cells of the tissues, undergoes certain chemical changes by which part of it is converted into fat, and part goes to the nutriment of the tissue cells. The cells can elaborate fat from any kind of food, but far more readily from some kinds than from others. I offer herewith some suggestions, and give a list of articles of food chiefly farinaceous which a person desirous of increasing his weight should confine himself to at the table. Sweet and Irish potatoes, sweet peas, beans, green corn, bread, tapioca, butter, liver, apples, arrowroot, barley, beets—these are very fattening. Crackers (especially sweet), cakes, carrots, grapes, gravies thickened with flour, the dressing of poultry, honey, maccaroni, oatmeal, parsnips, preserves and sweet fruits, rhubarb, sago puddings, all kinds of pastry, soup (thickened like mock turtle), mush and milk and mush fried and battered, mince pies, puddings of every kind, all fresh fruits, sweetened and with cream, ice cream and sauces, broths and melted butter, a lump of which should be put into all vegetables and used freely upon bread. A person dieting for corpulence who eats only lean meats may be allowed a little butter, as some fat is needful to the system; but if eaten immoderately butter is exceedingly fattening. Rice, though popularly supposed to be flesh forming, is not really so if we may judge of its qualities by those thin races of rice-eaters, the Hindoos and Chinese. Five articles of food may be said to be the foreordained means of building up fat. They are bread and butter, milk, sugar and potatoes. If you would wax fat eat candy, as much as thy purse can buy. Fanny Davenport blames the bonbon box for her obesity. Nothing of flesh, fish, fowl or fruit is forbidden to those in the pursuit of adiposity, but the oilier kinds of all eatables are to be preferred. Veal and pork rather than beef and mutton, goose and duck rather than turkey and chicken, and the oilier sorts of fish, such as eels and salmon. Eat only the yolks of eggs and all vegetables which contain sugar. Pumpkin, when made into pies, is very fattening. Do not eat cranberries, lemons, lettuce, spinach, cabbage (except the red, but not pickled; no pickles or pickled viands are allowed). Asparagus and tomatoes are for the consumption of the fat, not the lean, but to these are permitted cheese, lentils, all kinds of sweet and made dishes, rich gravies, thick sauces, corn meal in all its numerous forms, salep, sago, succotash, sucking pigs, bananas, and nuts of every kind that grows. Pleasant indeed are the ways that lead to corpulence. Its broad avenues may be named Eat Street, Drink Street, Sleep-and-Take-Your-Ease Street. You may feast on boiled chestnuts, doughnuts, griddle and buckwheat cakes, molasses, pineapples and cocoanuts. Eat only sweet oranges and all preparations of chocolate. Coffee is allowed. It has no effect either to fatten or reduce in itself, but can be rendered fattening by adding an excess of milk and sugar. A cup of hot chocolate, with milk and sweetened, taken nightly at bed time ought to put flesh on a skeleton. At meals drink milk, the thicker with cream the better. Use no vinegar nor acids nor cider. Take no lemonade nor tea. Milk punch is excellent, but should be drunk sparingly. Shakespeare says that use doth breed a habit in a man." He always knew what he was writing about, did Shakespeare. The daily recurrence of anything is what fixes it into a habit. Medicine taken one day and left off the next does no good, effects nothing. So it follows that the fattening process, once begun—to be effective—must be persisted in. Port wine is fattening, so are all malt liquors, especially lager beer. A friend of mine who was lean to emaciation had vainly tried to "flesh up," when she was recommended to drink a schooner of lager every day with her luncheon. She followed this pleasant prescription and by the end of a year was so bulky that she was obliged to forswear the beverage on account of obesity. To the lean are permitted as drinks champagne and other sparkling and sweet wines, especially port, which by the way is to blame as a rule for the obesity of English dames in high life, Sarah, Duchess of Marlborough, drank three glasses of port daily until her weight increased out of all proportion to beauty. It will be seen by the above list that a mixed diet, containing plenty of fats and starches, a little more albumen than is needed to maintain the equilibrium of fat and flesh should be eaten by the thin, and the surplus of albumen fat ought soon to make itself apparent in the form of the eater. At the same time, gorging one's self should not be indulged in. It is unnecessary, and, indeed, detrimental to the desired end. It should be fully understood that in the kind of food, rather than in the quantity, is the cause of the formation of fat to be sought. Weigh before beginning the fattening process and every week thereafter, being careful to wear the same amount of clothing on the scales. Determine just how much fat you require for your size and age and be careful not to exceed it, for while a moderate reserve of fat is good to draw upon in time of sickness, a large amount of it endangers the life in many ways. Obesity once started in the system is apt to increase of itself and steadily progress until checked. Therefore, upon the appearance of the first few pounds in excess of what you should weigh to be perfectly proportioned, abandon the exclusively fattening diet. To grow stout gradually, which is the better way, you should lead a calm, quiet, inactive, sedentary existence. Physical exertion works off superfluous flesh. In consequence of the deprivation of exercise convicts usually grow fat in prison. Corpulence is almost unknown among professional dancers and gymnasts, and among the Arabs and other nomadic tribes. Real mountaineers are never unduly fat, and wild animals are always lean, because they live in a state of constant movement. Do not imitate them, but rather the lazy lapdog which sleeps much and eats more of dainty, sugared little tidbits. Running, rowing and gymnastics are not for those who would be fat. Their exercise should be gentle and passive, riding rather than walking; they should be "wall flowers" in the ball-room and observers at the skating rink and swimming pools. If you would increase your adiposity, let the street car which is a few paces off go past without you. Quietly and contentedly wait for the next one. Patronize the elevator; when you must go up stairs take your time. Never bathe in water hot enough to cause perspiration. Keep cool, for the mind has much to do with getting fat, as well as in other matters. All the old time proverbs upon this subject refer to the mind more than to the body, such as "Laugh and grow fat," "Eat, drink and be merry;" not walk, jump, run and row and grow fat, but laugh and sleep. Sleep all you can and cultivate the practice of taking forty winks anywhere and everywhere. Above all, do not lie awake or pace the floor o' nights worrying about things. "Let the other man walk." Finally, drink no ice-water. Drink as little water as possible. You will be surprised to find how small a quantity is really required to satisfy the thirst. Water increases the size by bloating the body. Lager acts measurably in the same way. The increase caused by it is not owing to healthy flesh. It is hardly possible to give any idea of just how long it will take to fatten a person while following out the rules here laid down, as temperament and heredity differ so in individuals. One may have an inherited tendency to corpulence and fatten speedily, while all efforts will seem to fail with those to

whom leanness is a birthright. Nevertheless, a certain degree of plumpness can, in the long-run, be acquired by any one who perseveres in the diet and adopts the suggestions here given. Only two things can be positively stated about the fattening process. The first is that women are more disposed to corpulence than men because men lead, as a rule, more active outdoor lives than women. The second is that after forty—when every one is said to be either a fool or a doctor—both sexes "take on" flesh more easily than before that age. A little attention to dress, with a view either to increase or decrease the appearance of the real bulk, should be given by those afflicted with adiposity or the reverse. In costuming, the thin have the advantage over the fat. A lean man can hide his emaciation under loose pantaloons and large, easy fitting coats. The "skeleton dude," whose face is not gaunt, wears in the streets big garments, large coats, padded about the chest and shoulders so that he appears only a little thinner than the rest of mankind and not the "living skeleton" he is really. No such devices will conceal the too ample proportions of the fat man, who should never wear a dress coat—clawhammer—but a frock coat of rather easy fit and buttoned all the way down. No matter if tight trousers are the mode, his should always be somewhat wide. Too lightly fitting clothes are an abomination on stout persons. Nevertheless fat women, with servile subservience to prevailing fashions, attire themselves in gowns, etc., expressly designed to hide the deficiencies of thin women. For the modes of the last fifteen years we are indebted to two women, both lean, one extraordinarily so—the actress, Sarah Bernhardt, the other the Princess of Wales, whose neck it is said is so long and slender as to resemble a giraffe's. Hence all these elaborate throat frills and furbelows which are in vogue nowadays give an adipose woman the appearance of having her head seated directly upon her shoulders. Bernhardt is as great a genius in devising costumes as she is in acting, but her ingenuity is entirely expended in trying to deceive the eye as to her thinness. To hide her flail like-arms she introduced the wrinkled glove reaching to the shoulder. To her narrow shoulders we owe the hideous leg o' mutton sleeve, and to her long gaunt limbs and skeleton frame generally are due the thousand and one variations in draped skirts that have been rushed in and out of fashion for the last dozen or more years. We have to thank her for the bustle and hip draperies. One monstrosity alone she has spared us—the hoop skirt. With her strivings after the appearance of plumpness Sarah has novel ideas and an eye to the graceful and beautiful, but her creations are ludicrous when worn without modification by women whose too solid flesh will not melt nor be squeezed out of sight by tight lacing. What a picture a squat, podgy woman looks attired in the fashion of this year of our Lord, 1891! The short, full Medici cloak, which, falling just below the waist line, cuts the form in two, as it were, giving the effect of an Irish peasant's "short gown," breaking and shortening the line of the form, when the sought for effect should be long sweeping and unbroken. The present manner of draping the skirt is pretty and graceful on a slight figure, but when the material is stretched without a wrinkle over the broad expanse of the hips of a stout woman the width of flank it suggests is anything but pleasing. All the fullness of the skirt, and necessarily all the weight, is massed at the back, so that with the length it is hard for the obese woman to walk at all. The tight, long, armor-like waist encases her like a vise, hindering her breathing, except in gasps. The immense shoulder sheafs almost double in looks her already "a world too wide" shoulders. Only more unbecoming to full figures than the Medici cloak is the Medici collar, which reaches to the ears. Hats are too wide of brim and too low of crown to look well above double chins, heavy jowls and massive heads. There is hardly a prevailing style which was not expressly designed to increase the width of thin women, and stout women should modify them so that their defects of form will not be augmented by their attire. Stout ladies, let me entreat you to shake out a reef in the skirt so as to give the lower limbs room to move about without tugging at and straining the tether of tape in the rear of the dress. Let the waist be at least loose enough to be fastened without the aid of a button hook. Let the sleeves be only slightly full and drop carelessly away from the shoulders instead of being wired stiffly up almost to the ears. Lower the hard, high Medici collar sufficiently to show that although overly plump, nature has not denied you a neck altogether. Around the throat wear a single ruching or lace only scantily gathered in. Let a small shoulder mantle of jet or a half fitting jacket replace the ugly Medici cloak which, by the way, was not as a general thing worn by women but by men rather as an ornament than as a protection from the cold in the days when they wore doublets and hose, which reminds me of the movement now on foot to dress women in a similar manner to men. It is my belief that when, or if a great army of women should ever march forth in trousers, sack coats and the rightly named plug uglies of masculine wear, no fat women will be found in their ranks. Our fair, fat friend will draw the line at trousers, if wear them she must without her petticoat, that heirloom of the ages, worn by gentle and simple, old and young, and bequeathed from woman to woman, from generation to generation, from century to century, through all the vanished past. In every clime, time and country, woman has invariably worn some covering for the hips—it would seem a feminine instinct. It has borne many names, has changed from long to short, from scant to full, has been plain and adorned, but in some shape or other woman has never wholly abandoned the petticoat, and I think never will. However utilitarian and comfortable may be the male dress of the nineteenth century, there is a large majority of female forms for which it is especially ill adapted—the bent, scrawny grandmother; the deformed, the passe girl and the obese elderly woman. I fear me much that the ranks of the female dress reformers will be mainly recruited from those whose lankiness alone would make trousers appropriate wear—and then—may I not be there to see the army of the "lean and slippered pantaloons."

500,000 MILES A MINUTE.

AN ELECTRIC CURRENT GIRDLES THE GLOBE IN THREE SECONDS.

Philadelphia scientists are preparing to find out how fast an electric current travels. An experiment will be made, probably from the Franklin Institute, by connections over the Atlantic cable to Liverpool and return. A recent test appeared to show that an electric current is a slow coach as compared to light, being only able to get over to Europe and back in something like a second, or at the rate of only some four hundred thousand miles a minute, while light ambles along at a million-mile-a-minute gait. The Philadelphia scientists who are proposing to make further investigation are not satisfied to give up the record to sunlight, and hope to prove that the electric current, if not handicapped, is the swifter element. The most recent experiment was tried at McGill College, Montreal, says the Philadelphia *Record*. The current was transmitted in Montreal, was transferred to the cable at the Newfoundland cable station by means of Thomson's mirror galvanometer, sent across to the station at Liverpool, and returned to Montreal by the same method. The distance traversed, partly by overhead wire and partly by cable, was 8,000 miles. From the time the current left the key in Montreal until it returned to the receiver in the same office just 1 second and 1-20th of a second had elapsed; but the conditions were not as good as they might have been, hence the further experiment to be made here. The rapidity with which the current travels over short wires with no delay indicated unlimited possibilities in the direction of practical tests. Prof. Marks, of the Edison Electric Light Company, is authority for the assertion that if the globe was encircled with a continuous cable a current would travel the entire distance in a trifle over three seconds. At this rate a current would travel to the sun, covering the entire distance of 96,000,000 miles, in three and a half hours. "In this age of science," said one of the gentlemen who will participate in the experiments, "people have an idea that we know so much now there is nothing more to be discovered. Why, we are yet in our infancy as far as electricity goes. New discoveries will yet be made, and we will live to see them put into practical use, which will revolutionize the entire world. The experiment which we are about to make in telegraphy is only a feeler which will lead to other and more startling experiments. The establishment of telephone communications between the hemispheres is already being seriously discussed."

WEATHER SIGNS.

THE INDICATIONS FORMULATED BY THE N. Y. FARMERS' CLUB.

The formula of popular weather signs which is most kindly treated by the official observers is that adopted by the Farmers' Club of the American Institute a number of years ago: 1. When the temperature falls suddenly, there is a storm forming south of you. 2. When the temperature rises suddenly, there is a storm forming north of you. 3. The wind always blows from a region of fair weather towards a region where a storm is forming. 4. Cirrus clouds always move from a region where a storm is in progress towards a region of fair weather. 5. Cumulus clouds always move from a region where a storm is forming. 6. When cirrus clouds are moving rapidly from the north or northeast, there will be rain within twenty-four hours, no matter how cold it is. 7. When cirrus clouds are moving rapidly from the south or southeast, there will be a cold hailstorm on the morrow if it be in the summer, and if it be in the winter there will be a snowstorm. 8. The wind always blows in a circle around a storm, and when it blows from the north the heaviest rain is east of you; if it blows from the south, the heaviest rain is west of you; if it blows from the east, the heaviest rain is south 9. The wind never blows unless rain or snow is falling within 1,000 miles of you. 10. Whenever heavy white frost occurs, a storm is forming within 1,000 miles north or northwest of you. This is about as far as popular weather prophecy has yet advanced. It is not a great distance, but it is better than the old fashion of trusting to the italic warnings in the almanac, prepared a twelvemonth ahead: "*About these days look out for——*."

SAVE THE EYES.—All incandescent electric lights should be shaded for desk work. Since they have been generally introduced, it has been found that where the rays fall direct upon the eyes of newspaper writers and desk workers, there has been a great increase of complaints of dimness of sight and inflammatory affections of the eyes.

OUT OF HIS LINE.—Were one to take the patents which have been proved commercially unpractical, and trace them to the source from which they originate, it would be found—almost without exception—that the inventor was a man who had stepped out of his own business and had invented some wonderful thing in a line with which he was unfamiliar.—*Journal of Useful Inventions.*

A GOLDEN RULE.—Each one of us is bound to make the little circle in which we live better and happier; each of us is bound to see that out of that small circle the widest good may flow; each of us may have fixed in his mind the thought that out of a single household may flow influences that shall stimulate the whole commonwealth and the whole civilized world.—*Dean Stanley.*

ADULTERATIONS IN NEW HAMPSHIRE.

LAWS FOR THE SUPPRESSION OF ADULTERATED FOODS AND DRUGS.

AN ACT to prevent the sale of adulterated foods, drugs, and other articles.

Be it enacted by the Senate and House of Representatives in General Court convened.

SECTION 1. No person shall sell, or offer for sale, any adulterated drug or substance to be used in the manner of medicine taken internally or applied externally, or any adulterated article of food or substance to to be used in the manner of food or drink.

SEC. 2 If any drug or substance used for medicine sold under a name recognized by the United States Pharmacopœia, or under a name not recognized in that work, but found in some other pharmacopœia, or other standard work of materia medica, differs materially from the standard of strength, quality, or purity laid down in such work, or contains less of the active principle than is contained in the genuine article weight for weight, or falls below the professed standard under which it is sold, it shall be deemed to be adulterated within the meaning of this act.

SEC. 3. If any food or substance to be eaten or used in the manner of food or drink contains a less quantity of any valuable constituent than is contained in the genuine article weight for weight, or contains any substance foreign to the well-known article under whose name it is sold, or is colored, coated, polished or powdered, whereby damage is concealed, or contains any added poisonous ingredient, or consists wholly or partly of any decomposed, putrid, or diseased substance, whether manufactured or not, or has become offensive or injured from age or improper care, it shall be deemed to be adulterated within the meaning of this act.

SEC. 4. Whoever fraudulently adulterates for the purpose of sale any article of food or drink, drug or medicine, or knowingly sells any fraudulently adulterated article of food or drink, drug or medicine, or any kind of diseased or unwholesome provisions as defined in this act, shall be imprisoned not exceeding one year, or be fined not exceeding four hundred dollars, to be recovered by indictment for use of the county in which the offence was committed.

SEC. 5. The State Board of Health shall take cognizance of the interests of the public health relating to the sale of drugs and foods and the adulteration of the same, and shall make all necessary investigations and inquiries in reference thereto, and the analytical work acquired under the provisions of this act shall be made by the United States Experimental Station, and New Hampshire College of Agriculture and the Mechanic Arts.

SEC. 6. Every person offering or exposing for sale any drug or article of food within the meaning of this act, shall furnish to any analyst, or other officer duly appointed for the purpose, who shall apply to him for the same and tender him its value in money, a sample sufficient for the purpose of the analysis of any such drug or article of food which is in his possession.

SEC. 7. Any person who has reason to doubt the purity or genuineness of any article of food which he has purchased, may send at his own expense a sealed sample of it to the State Board of Health for inspection. If upon examination the article appears to be adulterated, said board may obtain a certified sample of it by whatever way seems best to them, and should this sample prove to be adulterated the board shall begin proceedings at once against the vendor of the article.

SEC. 8. Whoever hinders, obstructs, or in any way interferes with any inspector, analyst, or other officer appointed hereunder in the performance of his duty, shall be punished by fine not exceeding fifty dollars for the first offence, and one hundred dollars for each subsequent offence.

SEC. 9. Before commencing the analysis of any sample, the analyst shall reserve a portion which shall be sealed; and in case of a complaint against any person, part of the reserved portion of the sample alleged to be adulterated shall, upon application, be delivered to the defendant or his attorney, and part of the reserved portion of the sample shall be delivered to the secretary of the State Board of Health.

SEC. 10. The State Board of Health shall adopt such measures as it may deem necessary to facilitate the enforcement of this act, and for the collecting and examining of drugs and foods, articles of clothing, fabrics, wall paper, or anything containing poisonous pigments or substances whereby the health of any person wearing or using the same may be injured.

SEC. 11. Said Board of Health shall report annually to the governor and council the number and kinds of samples examined, together with the results of such examinations, the number of prosecutions made under this act, and an itemized account of all money expended in carrying out the provisions thereof.

SEC. 12. All acts and parts of acts inconsistent with this act are hereby repealed, and this act shall take effect upon its passage.

Approved April 7, 1891.

METEORITES.

SOME CONJECTURES RESPECTING THEIR ORIGIN.

In former times it was thought that meteorites were of terrestrial origin, thrown out by volcanoes, or condensed vapors, or else that they hailed from the moon. These suppositions do not hold good when we consider the enormous initial velocity, the great number, direction and periodical recurrences of these phenomena. For the same reasons, it is impossible that they should be fragments of a destroyed satellite—a second moon—supposed to have revolved around our planet in past ages, or yet that they are diminutive independent planets of our solar system. The hypothesis that they are identical with shooting stars and comets is the one accepted almost universally by scientific men. Most important discoveries tending to prove this assumption were made by Shiaparelli, showing that shooting stars, as well as meteorites, are solid bodies, which enter the atmosphere of our earth with an immense velocity and become luminous because of the resistance offered by the air. It has been calculated that they usually appear at a height of about seventy miles above the earth and disappear at a height of fifty miles. The cause of their disappearance or extinguishing is to be looked for either in their once more leaving our atmosphere, or that they are atomized by the fierce heat generated by their extremely rapid flight and the resistance offered by the atmosphere. The latter assumption would account for the continuous fall of cosmic dust upon the surface of our globe. The velocity with which they enter and pass through our atmosphere is enormous. It is many times faster than sound, the flight of a cannon ball, and even the planets revolving around the sun. The earth travels through space at the rate of 19 miles per second. Mercury the fastest planet, covers 29.87 miles per second, while a meteorite which fell at Pultusk, Russia, had a velocity of 33.78 miles per second, although it had to overcome the resistance of the air. In space, consequently, it must have traveled still faster. To clearly understand the high degree of velocity implied by these figures, it is well to add that the fastest cyclone scarcely reaches 150 feet per second, at which rate it exerts a pressure of about fifty pounds per square foot. It now remains to explain the assumption that meteorites and shooting stars are identical, and to quote the facts upon which this assumption is based. We know that both are solid bodies which enter our atmosphere from without, and that they become luminous for the same reason. Furthermore, the cosmic iron dust observed in localities where its origin could not be doubted has been found to have the same chemical composition as larger pieces of meteoric iron seen to fall by unimpeachable witnesses. It cannot be denied that there is a very great contrast between the little star that silently glides through space and noiselessly disappear and the terrifying appearance of a ball of fire, that, approaching with deafening detonations, sends down on us a hail of stones. Both spectacles, however, are but the extremes of a chain of closely connected phenomena. Considering with what extreme velocity these bodies pass through the atmosphere, it is not difficult to comprehend that particles, and those having the greatest momentum, are destroyed long before they reach the earth, and at such a height that the noise of their passage and disintegration becomes inaudible to us here below. We find a further confirmation for the belief that both of these phenomena have the same source in the well established fact, proved in many instances, that the direction of the meteorites corresponds to that of shooting stars observed at the same time, and points to a common point of radiation. The detonations acccompanying the fall of a meteorite have three distinct causes: The whizzing is caused by its rapid passage through the air; the crackling by the combustion of the materials composing it; and the thundering, by columns of air rushing into the vacuum which it leaves behind.—*Great Divide.*

ELECTRICAL POWER.

A FORECAST OF THE GREAT MECHANICAL POSSIBILITIES OF THE FUTURE.

The problem of the transfer and distribution of power, at this period, can scarcely be deemed of less economic importance than was the application of power itself. The importance of the problem may be seen at a glance if one only considers the incalculable horse-power of the Niagara Falls, or of the ocean in its changes between ebb and flow. The successful achievement of the transfer and economic application of the forces of nature would bring about a complete revolution of industrial conditions. The practical application of the principle which was exhibited at Frankfurt-an-Main on May 15th was simply as follows: In a machine so constructed that wire from insulated spools can be led over magnetic poles, an electric current is generated whose intensity and strain is dependent on the speed of the rotation and the power employed. The electric current thus generated is connected by two strong wires with a second machine of similar construction, the wire spools of which are set in motion by the electric current from the first machine. Theoretically it should now be possible to get as much power from the secondary dynamo as was employed in generating the current in the first or primary dynamo. The explanation is that an electric current being guided into a dynamo at rest will set its armature in rotation, and as the distance between the two dynamos, the generator and receiver, does not affect the result, the dynamo would appear to be an unexcelled apparatus for the transfer of power. And in fact no other method of transferring power can rival the electric system. The electric conductors can be laid to the most out-of-the-way places; they can be sunk as insulated cables in the earth, or in river beds, or they can be carried on poles like telegraph wires, by the aid of non-conductors, to the place where the second dynamo is to be employed in driving the labor machine. This capacity of the electric dynamo to transmit power by means of insulated wires, up hill and down, renders it eminently adapted for employment in mines, tunnels, and other works in the mountains, especially in the operation of wire tramways, on which principle a postal line between Monte Video and Buenos Ayres has been already designed. Speaking generally, the dynamo machine can be employed for all purposes for which steam and gas motors are at

present employed and with many enormous advantages. There are no boilers to heat, no waste of gas, it is ready for work at any moment. The electric current is drawn from electric works where electricity is stored in enormous quantities, and supplied cheaply; and, finally, with one touch of the hand the motor is set in operation. The amount of electricity employed is precisely proportioned to the labor performed, and, what is of prime importance, the electric motor, in relation to the importance of the work performed, is very easily operated. As regards the dreaded danger of powerful currents, this can be so thoroughly guarded against by transformers and accumulators, that it is really freer from danger than gas or steam. Of chief interest for the general public is the application of electric motors to the operation of street railway cars, a system which is already rapidly coming into use. And now as to the economic importance of this transfer of electric force. There are two primary sources of power on earth: The sun's heat stored up in wood and coal which we convert into steam; a very imperfect method inasmuch as from the imperfection of our machinery five-sixths of the actual power stored in the combustible is wasted. Moreover, this source of power must be carried to the place where it is intended to utilize it. The second source of power is the force generated by the rivers in their course, by the ebb and flow of the tides of ocean, by the winds. The utilization of these sources by means of dynamos in the manner above described has already had practical effect given to it on the small scale, but the method is now awaiting its crucial test at Frankfurt-an-Main, where arrangements have been made for the transfer of 300 horse-power from the Neckar. And as the system is operating satisfactorily on a smaller scale in many places in Switzerland, no doubt is entertained as to the success of this first experiment on a large scale. Should it work as satisfactorily as is expected, it will not be long ere the Falls of Niagara will be put into harness to drive the machinery of New York and Chicago. The French, too, have planned works at Havre for utilizing the ebb and flow of the tide to work turbine wheels which will transfer the power generated to dynamos, from which it will be conveyed by wire to Paris for motor and lighting purposes. The influence which this use of the vast forces of nature will exercise upon social and industrial conditions will be more apparent when we realize that it has other applications than the mere transport of motive power. The present condition of science leaves no doubt that any one form of motion can be transformed into any desired form—all the forces of nature into heat, light and mechanical power, as well as into electricity, and any one of these forms of motion into any other. Electricity is the form of motion most convenient for transfer into other forms, and with that at his command the possibilities of man's achievements transcend the dreams of fable and imagination. "Electra" is the fairy whose magic wand is already in motion, rearing pillar on pillar of the stately palace on which humanity shall sit enthroned, with all the forces of nature obedient to its behests. H. Lux.

NATIONAL CONTRASTS.

REPUBLICAN SIMPLICITY *versus* ROYAL DISPLAY.

There was a great deal of fuss and parade at Windsor Castle on Sunday. The tall, light-haired young man who styles himself the "war lord" of Germany was the guest of the motherly old lady whose State title is Victoria Regina, and soldiers and servants, gay ladies and lords whose breasts glittered with orders, were alike on the qui vive. The Kaiser took a carriage ride, and his equipage was surrounded from start to finish with outriders and gorgeously uniformed guards. He breakfasted with his grandmother, and the meal rose to the dignity of a State affair, with obsequious flunkeys by the dozen to see that everything went right' and watchful sentinels at every door to see that no McAllisters came near the quarters where their royalties took their chops and coffee. The Kaiser went to church, and a splendid array of plumed and bedizzened military attaches rode by the carriage. The English Life Guards, one of the finest, if not the finest, of the crack cavalry organizations of Europe, were paraded, inspected, and then fell in and solemnly escorted the Kaiser and his disreputable uncle, the Prince of Wales, to the place of worship. They waited, grim and stately, in stiff ranks, outside, while the services went on. Then, with the same precision and ceremony, the party went back to the castle again, making almost as brilliant, though not as instructive, a show as one of Barnum's circus parades. On the same morning the simple, unostentatious gentleman who is the President of the United States drove to church at Cape May with two members of his family, without any escort or fuss whatever, just as any other plain citizen might have done. Nobody expected the President at that particular church; nobody made any demonstration or display because he went there At the same time President Carnot, the official chief of the great armed French Republic, was addressing the scholars at a school for working men's children in Paris, having driven there unheralded and unescorted, as quietly and unostentatiously as President Harrison had driven to Cape May. The contrast between the royal and republican methods of going about is striking enough to impress the dullest mind. It is the contrast between sense and nonsense, between silly and vulgar and costly display, for which the people have to pay, and dignified, manly simplicity which costs the State nothing and sets its people an example to be proud of. It is calculated to make sensible and self-respecting Americans and Frenchmen heartily glad that they live under republican forms of government in which the head of the State is merely its first citizen.—*Press, July 7.*

DOMESTIC DIETETICS.

SPECIALLY PREPARED, FROM PRACTICAL TESTS, FOR THE LADY READERS OF THE "AMERICAN ANALYST."

SEASONABLE FOOD.
July.

MEAT.—Beef, lamb, mutton, ham, kidneys, liver, sausage, veal.

GAME AND POULTRY.—Pigeon, chicken, duck.

FISH.—Anchovy, bass, bluefish, blackfish, cod, eels, clams, flounder, haddock, halibut, herring, lobsters, mackerel, mussels, perch, porgie, prawn, salmon, shad, turtle, trout, sturgeon, whiting, weak-fish.

VEGETABLES. — Beans, cucumbers, carrots, cauliflower, egg-plant, lettuce, onions, parsley, parsnips, potatoes, shallots, spinach, turnips, radish, rhubarb, corn, beets.

FRUITS.—Cherries, strawberries, raspberries, huckleberries, melons, gooseberries, blackberries, peaches, pears, tamarinds bananas, pineapples.

PRACTICAL RECIPES.

OKRA SOUP.—Cover a leg of mutton with cold water, put with it four dozen okras and boil for an hour; then add six tomatoes, six small onions, one green pepper, a bunch of thyme and parsley, and let it boil seven or eight hours. Season it with salt and red pepper to suit your taste, and if agreeable add a piece of salt pork which has been previously boiled.

BOILED COD WITH OYSTER SAUCE.—Rub some salt over the fresh fish an hour or two before boiling; boil till done, then serve with the following sauce: Drain the liquor from a pint of oysters; beard the oysters and put the beards to cook with the liquor, adding a bit of mace and lemon peel. Throw the oysters meanwhile into some cold water, drain them after a few moments, strain the liquor and add it to them with a good lump of butter rubbed into a teaspoonful of flour. Cook until the sauce thickens, then add sufficient milk to make it the right consistency; boil up, add a squeeze of lemon juice and serve.

ONION OMELET.—Chop a small Spanish onion fine, and fry it a light brown in two teaspoonfuls butter; beat slightly four eggs and mix them with the onion; season with pepper and salt and cook; serve garnished with parsley.

YORKSHIRE PUDDING.—Beat thoroughly five eggs; add to them a teaspoonful of salt and a pint of milk. Sift together two teaspoonfuls of baking powder and a pint and a half of flour; add the egg mixture gradually and make a stiff batter; put it in the pan, not under but beside a roast of beef, and bake.

GINGERBREAD.—Beat together one cupful molasses, half a cup melted butter, half a cup milk, two and a half cupfuls flour, with which is mixed two teaspoonfuls baking powder, one teaspoonful ginger, one teaspoonful cinnamon, and a saltspoonful of cloves. Currants may be added if liked.

RICE BLANCMANGE.—Wash a pint of rice and boil it in a quart of milk until tender; add three ounces of sugar, and stir while cooking until the sugar is dissolved. Remove it from the fire, and when cold add the well-beaten yolks of five eggs. Soak one ounce of fine gelatine in cold water until soft, add to it three gills of boiling cream and two ounces of sugar; stir until dissolved, strain into a tin, which place in a wooden bowl surrounded with ice. When it commences to set whisk into it the whipped froth of three half-pints of cream, flavor with a few drops of extract, and work this into the rice mixture as lightly as possible. Put in the bottom of the moulds a tablespoonful of preserves or jelly, fill the moulds with the preparation and keep them on ice until wanted.

CURRANT JELLY.—Put your currants, freed from stems and leaves, into a kettle and heat, but do not boil them; remove them from the fire and mash the fruit so as to break every currant. Suspend the fruit in a flannel jelly bag, and set an earthen dish beneath it to catch the juice; when all is out, boil it in the preserving kettle with a pound of sugar to each pint of juice, skimming it as it cooks. Test it by putting a little in a saucer on ice, and if it thickens it is done. Put in glasses, cover with papers dipped in brandy, then with thick brown paper pasted down around the edge, or else use regular tin jelly glass lids.

IMPROVED WELDING.—A new welding method, invented by H. E. Fowler, New Haven, Conn., refers principally to lap-welds for joining the ends of band saws, plates and bars, and the manufacture of water-pipes, boiler-shells and the like. The process consists in first forming holes in one of the parts to be united, so that when the parts are heated and welded by any convenient means, a portion of the metal of the other part will be forced into said holes, strengthening the joint. In modifications holes are formed in both the parts to be welded, and in some cases these holes are made to coincide and pins or rivets are inserted.

WORLD'S PEOPLE.—In the proceedings of the Royal Geographical Society for January, 1891, it is estimated that the population of the world in 1890 was 1,487,600,000, representing an average of 31 to the square mile and an increase of 8 per cent. during the decade. Of the continents, Asia has the largest population, 850,000,000, and the lowest percentage of increase, 6 per cent. Australasia has the smallest population, 4,730,000, and the smallest average per square mile, 1.4, but the highest rate of increase during the decade, 30 per cent. Europe is the most thickly settled continent, with a population of 380,200,000, which is 101 to the square mile. The population of North America is estimated at 89,250,000, which is an average of 14 to the square mile, and represents an increase of 20 per cent. during the past decade.

FRUIT DIET.

THE PROPER USE OF THE SEASON'S GIFTS.

A trip through our public markets and among the commission houses along the side streets down town might cause a stranger to declare we must be a nation of fruit eaters, judging from the immense quantities and the infinite variety of fruits to be seen upon all sides. Pomona, the goddess of the fruit trees, reigns supreme, and is likely so to rule for the next few months. Notwithstanding the fact that the city is teeming with fruit, there are thousands of unfortunates who rarely taste fresh fruit. Some of them are charges upon the city and live upon charity; others there are who look upon fruit as a luxury and not a necessity, and live on coarse greasy foods until disease overtakes them and warns them to change their diet. It is absolutely necessary to teach some a severe lesson before they obey the laws of health. The Pacific coast is sending us peaches, plums, apricots, and cherries. The South is supplying us with melons, canteloupes, blackberries, green apples, grapes, pears, etc. Tropical America is stocking our fruit stalls and warehouses with bananas, pineapples, alligator pears, sapodilla plums, custard apples, cherimoyers, green or jelly cocoanuts, mammee apples, and many other fruits the names of which are unpronouncable. Yet better than all these are our native currants and raspberries. If the Board of Health should compel each inhabitant to eat at least a quart of currants daily there would be little use for the sanitary corps of that department. A more delightful breakfast invigorator than a combination of currants and raspberries would be hard to find. The tameness of the raspberry blends perfectly with the acidity of the currant. We may cook the currant in open tarts, but not the raspberry. The latter forms a tempting dessert served as shortcake; not the sweet shortcake of the shops, but the old-fashioned New England shortcake, made with sour milk, in the absence of which baking powder is used. To prepare it: Sift together half a pound of flour, a coffee spoonful each of salt and sugar, and two teaspoonfuls of baking powder. Work into this mixture a quarter of a pound of cold washed butter; add gradually two gills of cold boiled milk; mix quickly with a knife; dredge flour over the molding board, and turn the paste upon it; toss with the knife until it is floured; pat it gently with a floured rolling pin, and roll it down to half an inch thickness; put a plate on top of the paste and cut round it. Grease a baking tin, put the rounds upon it and bake. When done, make an incision round the centre of the edge and tear apart. If not too thick, they need not be divided. Arrange a layer of the berries on one-half of the cake, dredge with fine sugar, and place the other half on the berries; cover the top with the largest berries, as restaurant people do, add a liberal quantity of sugar, and serve. A mixture of whipped white of egg and sugar is sometimes added to the top layer, and is placed in the oven a moment to set, but too much heat will spoil the berries.—*Sun.*

INTELLECT AND DIET.

THE TABLE HABITS OF SOME OF THE WORLD'S GREAT MEN.

We find in the *Gentleman's Magazine* some interesting, suggestive and pleasantly anecdotal papers on "Living to Eat and Eating to Live," whence we extract the following: Great men are always credited with being abstemious in their eating and drinking, and the first Napoleon was no exception to the rule. Describing the food which was placed on his table to his physician, Dr. Atommarchi, he said: "Physicians have the right of regulating the table; it is fit I should give you an account of mine. Behold what it consists of: a basin of soup, two plates of meat, one of vegetables, a salad when I can take it, compose the whole service: half a bottle of claret, which I dilute with a good deal of water, serves me for drink; I drink a little of it pure towards the end of the repast. Sometimes, when I feel fatigued, I substitute champagne for claret: it is a sure means of giving a fillip to the stomach." The doctor having expressed his surprise at this temperate mode of living, he replied: "In my marches with the army of Italy, I never failed to put in the bow of my saddle a bottle of wine, some bread, and a cold fowl. This provision sufficed for the wants of the day; I may even say I often shared it with others. I thus gained time: the economy of my table turned to account on the field of battle. For the rest, I eat fast, masticate little; my meals do not consume my hours. This is not what you will approve the most, but in my present situation what signifies it?" He was referring here to his captivity at St. Helena. The daily habits of the poet Southey, a man who made literature a successful and healthy profession, are thus described by his son in his life of his father. "Breakfast was at nine, after a little reading, dinner at four, tea at six, supper at half-past nine, and the intervals filled up with reading or writing, except that he regularly walked between two and four, and took a short sleep before tea, the outline of his day when he was in full work will have been given. After supper, when the business of the day seemed to be over, though he generally took a book, he remained with his family, and was open to enter into conversation, to amuse and be amused." This rational mode of living deserved its reward: temperance, soberness and chastity preserved his mental powers vigorous to old age, and he has left to future generations work that will keep his memory green. Shelley was a vegetarian and an idealist. Perhaps, if he had been a meat eater, his verses would have displayed more passion and fire, for the contrast between his poetry and Byron's is striking, though Byron himself attributes his best work to the inspiration of gin-and-water. Byron's life is a melancholy example of how soon the candle that is lit at both ends

Buffalo Lithia Water, Spring No. 2, in Bright's Disease, Gout, Stone in the Bladder, and Diseases Generally of Uric Acid Diathesis, Etc., Etc.

DR. WM. A. HAMMOND, of Washington, D. C., Surgeon General U. S. Army (retired), Professor of Diseases of the Mind and Nervous System in the University of New York, etc.

"I have for some time made use of the BUFFALO LITHIA WATER in cases of AFFECTIONS of the NERVOUS SYSTEM, complicated with BRIGHT'S DISEASE OF THE KIDNEYS or with a GOUTY DIATHESIS. *The results have been eminently satisfactory.* Lithia has for many years *been a favorite with me in like cases, but the* BUFFALO WATER CERTAINLY ACTS BETTER THAN ANY EXTEMPORANEOUS SOLUTION of THE LITHIA SALTS, and is, moreover, better borne by the stomach. I also often prescribe it in those cases of CEREBRAL HYPERÆMIA resulting from OVER MENTAL WORK—in which the condition called NERVOUS DYSPEPSIA exists—*and generally with* MARKED BENEFIT."

DR. WM. B. TOWLES, Professor of Anatomy and Materia Medica, in the Medical Department of the University of Virginia.

"BUFFALO LITHIA SPRINGS, No. 2, belongs to the ALKALINE or, *perhaps, to the* ALKALINE SALINE Class, *for it has proved far more efficacious in many diseased conditions than any of the simple* ALKALINE waters.

"*I feel no hesitancy whatever in saying that in* GOUT, RHEUMATIC GOUT, RHEUMATISM, STONE *in the* BLADDER, and in all diseases of URIC ACID DIATHESIS, *I know of no remedy at all comparable to it.*

"*Its effects are marked in causing a disappearance of* ALBUMEN *from the urine. In a* single case of BRIGHT'S DISEASE *of the* KIDNEYS, I witnessed *decided beneficial results from its use, and from its action in this case I should have great confidence in it as a remedy in certain stages of this disease.* In DYSPEPSIA, especially that form of it in which there *is an excessive production of* ACID *during the process of nutrition,* in some of the PECULIAR AFFECTIONS *of* WOMEN, notably in SUPPRESSION of the MENSES, and in CHRONIC MALARIAL POISONING, etc., I have found it highly efficacious."

DR. G. HALSTEAD BOYLAND, late Professor of Surgery, Baltimore Medical College, late Surgeon French Army (Decorated), Member Baltimore Academy of Medicine, Member of American Medical Association.

"In BRIGHT'S DISEASE of the KIDNEYS, ACUTE or CHRONIC, BUFFALO LITHIA WATER, Spring No. 2, is, in my experience, *without a rival,* whether in the PARENCHYMATOUS form or INTERSTITIAL NEPHRITIS. In cases in which the ALBUMEN in the URINE reached as high as 50 per cent., I have known it under a course of this water gradually diminish and finally disappear, at the same time other alarming symptoms were relieved and the sufferers restored to health.

"In STONE in the BLADDER of the RED LITHIC ACID and the WHITE PHOSPHATIC DEPOSIT, the SOLVENT power of this water is *unmistakable.*"

Water in cases of one dozen half gallon bottles, $5.00 f. o. b. here.

THOS. F. COODE, Proprietor, BUFFALO LITHIA SPRINGS, VA.

burns out. Byron's horror of corpulence drove him to dietetic expedients to avoid it that certainly tended to shorten his life, such as chewing tobacco to stave off hunger and the desire for food, taking inordinate quantities of vinegar, and other questionable methods. Had he lived in these days he could have been told how to keep down fat and still live well, and enjoy most of the luxuries of life. Walter Scott passed a genial social existence, took plenty of exercise, lived temperately, and insisted on having seven or eight hours of sleep out of the twenty-four; hence he lived to a good age and did more work—that bears in every page of it the impress of genius—than any man of his day. Burns, his equally gifted countryman, lived to eat and drink, and hence the result. It is true he left poetry behind him that the world will not willingly let die; but what might he not have done? The high, strong, nervous system of the poet and literary man bears excess badly, and Swift seemed to know this, for in a letter to Pope he says: "The least transgression of yours, if it be only two bits and a sup more than your stint, is a great debauch, for which you will certainly pay more than those sots who are carried dead drunk to bed." The machinery of sensitive souls is as delicate as it is valuable, and cannot bear the rough usage that coarse custom inflicts upon it. It is broken to pieces by blows which common natures laugh at. Equally, when we descend into the lower regions of Parnassus, the abode of talent and cleverness, the care of the body is absolutely essential to long life and continued usefulness. He who lives by his intellect must take care of his stomach, for, after all, "mind is matter and soul is porridge."

ALABAMA OYSTERS.—Alabama owns about four square miles of oyster beds, "and these beds are amongst the most valuable in the United States. Every barrel of oysters taken out of the State is to pay a tax of ten cents, which will pay the expense of inspection and put into the State treasury about $15,000 a year."

Exhaustion

Horsford's Acid Phosphate.

The phosphates of the system are consumed with every effort, and exhaustion usually indicates a lack of supply. The Acid Phosphate supplies the phosphates, thereby relieving exhaustion, and increasing the capacity for labor. Pleasant to the taste.

Dr. A. N. KROUT, Van Wert, O., says:

"Decidedly beneficial in nervous exhaustion."

Dr. S. T. NEWMAN, St. Louis, Mo., says:

"A remedy of great service in many forms of exhaustion."

DESCRIPTIVE PAMPHLET FREE.

RUMFORD CHEMICAL WORKS,
PROVIDENCE, R. I.

BEWARE OF SUBSTITUTES AND IMITATIONS.

CAUTION:—Be sure the word "Horsford's" is *printed* on the label. All others are spurious. Never sold in bulk.

BUSINESS NOTES.

HORSFORD'S ACID PHOSPHATE

Makes delicious lemonade. A teaspoonful added to a glass of hot or cold water, and sweetened to the taste, will be found refreshing and invigorating. Dr. T. C. Smith, Charlotte, N. C., says: "It is an invaluable nerve tonic, a delightful beverage, and one of the best restorers when the energies flag and the spirits droop."

SAME BRAND.—She said to her grocer: "I bought three or four hams here a couple of months ago, and they were very fine. Have you any more like them?" Grocer: "Yes, ma'am. There are ten of those hams hanging up there." "Are you sure they are all off the same pig?" "Yes, ma'am." "Then I'll take three of them."

OLD-TIME BREAD.—The bread most commonly used by tradesmen in early days was made of barley, or rye mixed with peas. The finest bread was then called "simnel," the next class was "tourte," made of unbolted meal. "Irate" was bread made from wheat with the fine flour removed, and the commoner kinds were all sorts, black bread, and horse bread. These kinds of bread were in common use five centuries ago.

COCOA ADULTERATION.—Attention has been directed lately by the English papers to the alleged mischief resulting through the use of cocoas adulterated by added alkalies. Dr. Sidney Ringer, of University College, says in his work on Therapeutics that the sustained use of alkalies impoverishes the blood. There seems no reason for adding alkalies, except to give an appearance of fictitious strength.

NO SOAP.—It is stated that soap in India is regarded almost in the light of a natural curiosity, for it is rarely, if ever, to be obtained of a shopkeeper there. Of course it is sold in the larger towns; but the amount used by the natives must be very small, seeing that the total consumption of soap in India last year was only 5,000 tons. This means that the amount used by each person for the year was considerably less than one ounce.

FLOWERS IN LONDON.—It is said that during the London season some £5,000 are expended daily on cut flowers. On flower decorations for a big dinner party wealthy Americans will lavish hundreds of pounds. At a ball given recently by a rich merchant in honor of his daughter's coming of age, the portières separating the ball and supper rooms were made entirely of trails of stephanotis and of the delicate foliage known in Madeira, where it grows wild, as "Joy of the Country." The fragrant curtains were looped back with choice gardenias. The bill for decorations on this scale would, of course, work out to some hundreds of pounds sterling.

PULPIT AND BAR.—We have heard a good deal lately about reform in public-houses, but the most practical reformer is the rector of Hampton Lucy, England, who, according to the *Daily Chronicle*, personally owns and manages an inn, and that with the best results. He sells only the purest drinks, and is so careful to whom and in what quantities he sells them that drunkenness is unknown in his parish, whilst the local charities are fairly increased by the profits of the house, which are devoted to them. Hitherto, combined catering for spiritual needs and for spirituous ones have hardly been thought suitable for the same individual. But this may be only prejudice. The *fin de siècle* caterer ought to possess some original features.

DO TELL!—The following amusing bit of information we clip from *The Caterer* of London, for June. It appears that the base-ball players in America are in the habit of going about with their spiked shoes on. This curious custom has led the proprietor of the Continental, one of the first hotels of Philadelphia, to refuse to entertain them unless they desisted from the practice, obviously destructive to the fine carpets in the rooms and halls of the hotel. The players, however, transferred their patronage to another establishment. Yankees seem to advance but slowly in civilization. In Charles Dickens' time they freely expectorated on the best carpets. That habit they have since got rid of, and perhaps they will by and by come to learn that spiked shoes are not the proper thing to wear in a first-class hotel.

ORIGINAL. No. 70.

Virginia Corn Bread.

BY MRS. F. L. GILLETTE,
Author White House Cook Book.

Two teaspoonfuls Cleveland's Superior baking powder; two cupfuls white corn meal; one cupful flour; one teaspoonful salt; one tablespoonful sugar; two tablespoonfuls melted butter; three eggs; two and a half cupfuls milk.

Sift together all the dry ingredients, rub in the butter; then add beaten eggs and milk. Mix well and pour into round, buttered pans. Bake from thirty to forty minutes.

Use only Cleveland's baking powder, the proportions are made for that.

"Owing to the purity, strength, effectiveness and constancy of composition of Cleveland's Superior Baking Powder, I have adopted the same for use in my home."

Dr. Mott, late U. S. Gov. Chemist.
July 23, 1890.

PURE PEPSIN

In Powder and Scale.

MANUFACTURED BY

ARMOUR & COMPANY, Chicago.

Guaranteed free from adulteration or make-weights; of excellent physical properties and high digestive power.

Under similar conditions, **ARMOUR'S PEPSIN** will exhibit greater activity than any other pepsin now before the profession.

The Manufacturers will be pleased to supply members of the Medical Profession with samples of their pepsin, and with full details regarding digestive strength, if desired.

SEE PAGE 320 FOR VALUABLE OFFER.

WATCHES.

EVERY one wants a watch, and naturally a good watch that keeps accurate time, presents a handsome appearance, and is inexpensive. If such a watch can be found of American manufacture, it is an additional appeal to our patriotism. Just such a watch as this ideal THE ANALYST PUBLISHING COMPANY is enabled to offer as a Premium to its readers. Having some large advertising contracts we have been enabled to procure the movements of the manufacture of the best known American watch factories, namely, the Waltham, Elgin, Hampden and Illinois Watch Companies. These movements are adapted for both ladies' and gentlemen's watches, and are warranted by the makers. These movements have seven jewels, patent lever movement, chronometer balance, patent safety pinion, sunk hard-enameled dial, straight line visible palette, stem winders, hand set; in fact, contain all the latest improvements and can be readily cleaned or repaired by any ordinary good watchmaker. They can be regulated to run as close as any movement.

It is needless to say that to case these movements in solid gold cases would make them too expensive, yet they are cased in what are known as gold filled or stiffened "Ladd" cases, and are warranted to be 14 karat gold, made from two sheets of 14 karat gold overlaying fine composition metal, with regular jointed caps, covers and bezels, and to wear at least five years. They are not plated, nor rolled gold, but actual 14 karat gold cases, thin of course, but stiffened and strengthened by being filled with this fine composition metal. They are finished in the same manner, engine turned and engraved as solid gold watches, and wear and look just the same. No one but an expert can tell them from a solid gold watch. These watches are made both open face and hunting case style, in gentlemen's or ladies' sizes. For gentlemen we recommend plain engine-turned cases; for ladies, a handsomely engraved case.

How to Obtain One of these Watches.

These watches are not to be purchased from us at any price. Send us a club of 25 subscribers to the AMERICAN ANALYST, and $25, the regular subscription price, and one of these watches (your choice of style and size) will be immediately forwarded, post-paid and registered, to your address. You need not wait until you have your 25 subscribers all together, but forward them as you get them and they will be credited to you, and when the number is complete the watch will be sent. A subscription for two or three years will be counted as two or three subscribers.

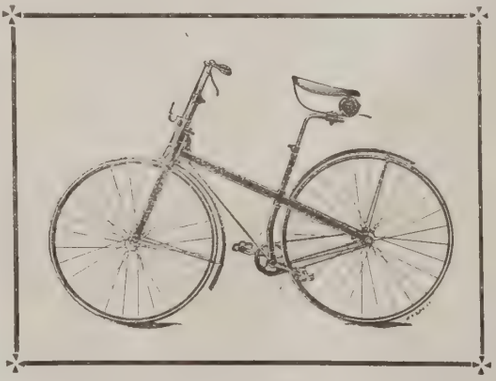
As these watches are retailed by jewelers at not less than $25, it will be seen that we are offering a real premium with the sole object of increasing our circulation, and that by taking advantage of our offer any one can obtain a good, reliable and handsome watch without cost. As the number of these watches at this price is limited, it is advisable to take steps at once to procure a bargain.

THE ANALYST PUBLISHING CO., 19 PARK PLACE, NEW YORK.

BICYCLES

GIVEN AWAY TO BOYS AND GIRLS!

AN OPPORTUNITY OPEN TO ALL.



The Analyst Publishing Company being desirous of largely increasing their subscription list, will furnish every one with a beautiful Safety Bicycle, ABSOLUTELY FREE, in return for a few hours' canvassing.

To every boy and girl who secures 75 subscribers for the American Analyst at $75, we will give a splendid

$40.00

NONPAREIL

SAFETY BICYCLE.

These bicycles are adapted in size to boys, but are strong enough to carry a man. A boy's bicycle should be a strong one. They are manufactured by the OVERMAN WHEEL CO., the makers of the celebrated VICTOR Bicycle, and have the full guarantee of the makers.

The following is a brief description of the NONPAREIL SAFETY; 26-inch wheels; ball bearing all around, including pedals; solid crescent rims; double-tangent spokes; three-fourths inch tires; cranks, three throw, $4\frac{1}{4}$ to $5\frac{3}{4}$ inches; guards to both wheels; tool-bag, oiler and wrench. Finished in bright enamel, all exposed metal heavy nickel-plate on copper.

In selecting these machines as a premium, we have disregarded cheapness and selected a Bicycle which is serviceable, and the makers of which have an established reputation for building the best Bicycle that money, machinery and brains can produce. We are actually furnishing the Bicycles and Papers at less than cost, but hope by stimulating active and successful canvassing, and thus enlarging our subscription lists, to make an eventual profit. We positively guarantee these bicycles to be just as here represented. They will be shipped by express f. o. b. in New York.

Subscription orders must be made out plainly and legibly, and sent as fast as secured, addressed to

THE ANALYST PUBLISHING CO., 19 Park Place, New York.

ONE YEAR FREE.

If you will send us the addresses of Twenty-five Ladies in your neighborhood to whom we can send sample copies of the **AMERICAN ANALYST,** we will send this paper to you free for One Year; or, for Fifteen names, Six Months; or, for Ten names, Three Months. We do this because our past experience assures us that any lady who once becomes acquainted with the value of the **AMERICAN ANALYST,** continues to subscribe for it. We also offer valuable premiums for raising clubs.

TABASCO PEPPER SAUCE,

OR LIQUID PEPPER.

Is simply the Pulp of the Ripe Pepper Extracted by Pressure.

The seed of this Pepper was obtained from Central America, and by careful cultivation in Louisiana for many years has been so improved in strength, flavor and aroma, as to have become a new variety of Red Pepper, superior to all others. The pulp is so handled as to retain all the flavor, strength, aroma and color of the ripe fruit, and to keep unimpaired in any climate. It excites the appetite, promotes digestion, and is pronounced by connoisseurs to be the finest condiment in the world. For medicinal purposes it recommends itself by its purity, strength and diffusible form.

Manufactured by E. McILHENNY'S SON,

NEW IBERIA, LA.

For Sale by all Wholesale Grocers.

NATRONA BI-CARBONATE OF SODA.

(ABSOLUTELY PURE.)

The nature of the raw material from which NATRONA BI-CARBONATE OF SODA is made—viz., kryolith, a mineral containing *pure sodium*—insures a purity and uniformity of product which cannot be obtained from any other known material. In making BI-CARB. SODA from any other raw material, the use of sulphuric acid is a necessity, but none is used in any part of the process of making NATRONA BI-CARB.; hence its entire freedom from the slightest trace of arsenic, which is always present in ordinary soda. I s absolute purity and entire freedom from all traces of *sulphate of soda*, common salt and other impurities, render NATRONA BI-CARB. NEARLY TASTELESS, and being bolted through the finest bolting-cloth, insures the finest stage of division.

To these indisputable facts the attention of CONSUMERS of soda is specially called. They are IMPORTANT, and should influence both those who use and those who sell soda, to buy and sell NONE BUT THE BEST.

The NATRONA BI-CARB. Soda is kept in stock by almost every wholesale druggist and grocer throughout the United States, of whom it may be ordered.

Natrona Bi-Carb. Soda is unequaled by any other brand of English or American Manufacture.

INSTRUCTIONS TO SUBSCRIBERS.

The **Names of all Subscribers** are registered as soon as received, and paper is always promptly forwarded.

Postage.—The postage to all parts of the United States and Canada is paid by the publisher.

Remittances of small sums may be made with comparative safety in ordinary letters. Sums of one dollar or more must be sent by registered letter or P. O. money order, otherwise we cannot be responsible for same. Silver must not be sent in a letter.

Postage Stamps will be received for the fractional part of a dollar, and in any amount when it is impossible for patrons to procure bills, but you must send one or two-cent stamps only.

SUBSCRIPTIONS.—The AMERICAN ANALYST will be sent one year to any subscriber for ONE DOLLAR. New subscriptions can begin at any time.

We Stop the Paper at the expiration of the time paid for unless a renewal of subscription is received. Those whose subscriptions have expired must not expect to continue to receive the paper unless they send the money to pay for it.

Change of Address.—Subscribers wishing their addresses changed must invariably give their former as well as new address.

Missing Numbers.—It occasionally happens that numbers of our paper sent to subscribers are lost or stolen in the mails. In case you do not receive any number when due, write us a postal card and we will cheerfully forward a duplicate of the missing number.

Most Important of All.—In every letter that you write us, never fail to give your full address, plainly written—name, post-office, County and State.

THE FLOODED DESERT.

The mystery of the deluged desert in southern California, mentioned in our issue of July 9, has been solved. There seems to be no question that this water comes from the overflow of Colorado River, which, having worn away its western barrier at a certain point, is emptying a vast volume of water into the great basin of the desert, which is set down on all maps as being at the ocean's level and the bed of an ancient lake. The lowest level is reached at Salton, on the Yuma Division of the Southern Pacific railroad, about 150 miles southeast of Los Angeles. Salton is in a vast depression which lies 160 feet below the sea level, covering an estimated territory of three thousand square miles. While exploration of railroad men has given the public at a distance official information on the subject there has never been the slightest doubt in the minds of "old-timers" in the vicinity that the source of the lake was the Colorado River. They say that in 1850 there was a similar inundation, only that the water did not reach so high a point as at present. Major Powell, the director of the United States geological survey, and a frequent explorer of that region in earlier days, believed that the great river was the source before any exploration had been made. This great valley, extending all the way from the Mexican boundary north and northwest, is but a continuation of the valley of the Gulf of California, and is 140 miles long by 70 miles wide. It is also a well-established fact that ages ago the ocean or gulf extended inland a considerable distance, covering the entire territory which now forms the most desolate portion of the desert. The old beach line of this sea may be traced for many miles on the mountain sides, while the bones of whales, shells of salt-water fish and other evidences of marine life are abundant. Singularly enough, in some places the remains found are those of fresh water fish, showing that the basin has been filled at times with both salt and fresh water. The vast deposits of salt now being mined at Salton were undoubtedly produced by the evaporation of the salt water, and explain the fact that the waters of the new lake are very salt. What the effect of the permanent flooding of a large area of the desert would be upon the climate can only be conjectured. That it would be favorable is unquestioned. For many years it has been a favorite project among French scientists to flood large areas of the Sahara, with the design of so ameliorating the climate of the remainder as to make it fit for habitation of man. That such a result would follow has been indisputably proven. There would unquestionably follow a heavier rainfall; even the times of precipitation might change. Certainly the fierce wind currents caused by the tremendous evaporation in the burning waste would cease. The territory surrounding the body of water would experience a most grateful climatic revolution, and with the aid of irrigation would become fruitful. The only interests which could be affected at all disastrously, from present appearances, would be those of the railroads. Should the water continue to rise, and finally reach the sea level, it would be necessary for the railroad to take to the hills to the northward. There are ranges of mountains there along whose lower slopes a road could readily be built above high-water mark.

AN IMPORTANT SUGGESTION.

A description is given by the *Popular Science News* of a slight modification of the present system of weights and measures proposed by Mr. Hannssen, a Danish engineer, by which it can be converted into a true decimal system equally convenient for calculations with the French metric system now so extensively used. Such a scheme, if producible, would be of universal ability. It is described by our contemporary as follows: "Briefly stated, the foot is increased by about 1-2,500 of its present length, or the thickness of ordinary note paper—exactly from 1.0000 to 1.000403—while the pound avoirdupois, the ounce, and the imperial gallon remained unaltered. By this very slight alteration of the length of the foot, which hardly will be noticed in trade, manufacture and commerce, the present system of standards is at once converted into a decimal system. While the present cubic foot only contains 436.971.78 grains of distilled water, the new standard cubic foot would contain exactly 1.000 ounces (437,500 grains) of distilled water of 4 deg. C. temperature; 16 cubic feet consequently will be equal to 100 gallons (called 1 hectogallon), and 1 hectogallon of distilled water of 4 deg. C. weighs 1,000 pounds. The new standard foot will be divided into deci-, centi- and milli-foot; and all the other units of weight and measure are correspondingly simplified. The new system is described very fully in a recent number of the *Chemical News*, and Mr. Hannssen has certainly hit upon some very curious and remarkable relations between our present standards of weight and measure, The difficulty experienced in introducting the metric system into general use shows how hard it is to make any change in this direction; but the slight actual alteration from existing standards required by this system, and the great ease and simplicity introduced by it into all calculations, may serve to render it more popular and generally acceptable if further discussions of the subject show no other objection to its general adoption.

INSPECTING AMERICAN MEAT.

The effect of the new meat inspection law is already apparent in the increasing demand for American meat products for the European market, and the indications are favorable for a speedy removal of the restrictions which have so seriously crippled our export trade in those commodities. Secretary Rusk, of the Department of Agriculture, and Dr. Salmon, Chief of the Bureau of Animal Industry, put the inspection work under the new law on a solid basis during a visit last month to Chicago. The inspection of beef carcasses has already been going on to some extent at New York, Chicago, Omaha and Kansas City, but the microscopic inspection of hog products only began on June 22d, after the Secretary and Dr. Salmon had organized the work according to scientific methods. This inspection will be carried on for the present only at Chicago, where the force is sufficient to inspect 600 hogs daily. A force of some thirty persons has been appointed, with salaries ranging from $1,000 to $1,800 for the microscopists, and smaller pay for young men and girls who affix labels and do other mechanical work. The chief microscopist is a person of scientific training, but such training is not thought necessary for all the inspectors, as they are soon able to learn the use of the microscope and to detect trichinæ where they are present. The cost of the inspection per animal will range somewhere between five and ten cents. The Depart-

ment of Agriculture has not yet undertaken to enforce strictly the provision of the law of March 3, 1891, that meats shall not be exported which have not been inspected. The enforcement of this provision at present would limit the export trade in hog products to Chicago, because no inspection force has yet been set at work at other points. If the experiment succeeds well at Chicago and the appropriation permits, inspectors will be appointed at other places. For the present the exportation of meats which have not been inspected is not interfered with, but it is not likely to be large, because none but the inspected meats find a ready market on the other side of the ocean. The appropriation made for the Bureau of Animal Industry for the coming year was made before the new inspection law was passed, and will not permit a great extension of the service. The appropriation will probably be increased by the next Congress, with its large membership especially favorable to the farming interest, if the new law has the intended effect of increasing our export trade in beef and hog products. The total appropriation for the Bureau for the coming fiscal year is $500,000, an increase of about $50,000 over the amount available for the year just closing. The advices received by the State Department indicate that France and Germany will remove their restrictions upon the importation of our meat products about October 1st. It is believed that the inspection law will be in full force by that time.

PATRES PATRIÆ.

WHO WERE THE FATHERS OF THE REPUBLIC?

We reprint the subjoined bit of national history from the columns of the *Illustrated Christian Weekly* as a wholesome and instructive reminder of some of our illustrious predecessors of revolutionary times: "The Declaration of Independence is probably the most important event in the annals of our country. It is one of the great events in the history of the world. The men who were the actors on this occasion, whose names are appended to the immortal document, have been called the 'Fathers of the Republic.' Some of these men were raised to fame by the mere fact that they were signers of our Magna Charta; but the greater number of them were leading men of the colonies, and took a prominent part in the events that followed. A few facts relative to the event and to the illustrious body of men who imperilled their lives and fortunes by attaching their signatures to that instrument, which established our national independence, may be of interest before we refer particularly to the more prominent actors. The United States, then comprising the American colonies, were represented in the assemblage that passed that measure by fifty-eight members. The President, John Hancock, was the only one, however, who signed the document on the 4th of July, 1776. On the second day of August it was signed by all but one of the fifty-six of the signers whose names are appended to it. The other, who was Matthew Thornton, of New Hampshire, attached his signature in November. Henry Wisner, one of the New York delegation, was present when Congress expressed its approbation of the Declaration, and voted in favor of it; but before the engrossed copy was signed by the several members Mr. Wisner left Congress, and thus failed of affixing his name to this memorable paper. Another member of the New York delegation who missed affixing his name to the historical document was Robert R. Livingston, who was prevented from signing that instrument by an enforced absence from Philadelphia. When the vote was taken upon the question, it was recommended to begin with the northernmost colony. Dr. Josiah Bartlett, of New Hampshire, therefore, had the honor of being called upon for an expression of his opinion, and of first giving his vote in favor of the resolution. He was also the first to affix his signature after Hancock. Hancock's is the handsomest and boldest of all the signatures attached to the Declaration; the others look weak and cramped beside it. But not one was written with a trembling hand except Stephen Hopkins's, of Rhode Island, and it was not fear that made him tremble, but the palsy, from which he was a sufferer. Charles Carroll was the only member who added his place of residence, and the reason of his doing this was somewhat peculiar. When Carroll was signing, some one near him remarked, 'There are several of your name, and if we are unsuccessful they will not know who to arrest.' 'Not so,' replied the Maryland millionaire, and immediately added, 'of Carrollton.' He lived to see all the memorable men with whom he acted on that eventful day pass away, and enjoyed the prosperity of his country until 1832, when he died at the advanced age of 95 years. The larger number of the signers were comparatively young men, for the average of all was 43 years and 10 months. Edward Rutledge, of South Carolina, was the youngest of the fifty-six, being only 27. The Nestor of the body was Benjamin Franklin, of Pennsylvania, who was 70. The most opulent was Charles Carroll, who was considered the wealthiest untitled man in the colonies. Robert Morris, of Pennsylvania, came next, and then probably John Hancock. Samuel Adams, of Massachusetts, was the poorest, his impoverished condition being well known. The others were all in easy circumstances. There were five physicians among the signers. Thirty of them were lawyers, seven were farmers, eight were merchants, two were mechanics, one was a clergyman, John Witherspoon, of New Jersey. Abraham Clark, of New Jersey, was a surveyor; Roger Sherman, of Connecticut, was a shoemaker, and Franklin boasted of being a printer. With the exception of eight, all the signers were natives of American soil; of these two—Robert Morris and Button Gwinnett, of Georgia—were born in England; Matthew Thornton, of New Hampshire, and James Smith and George Taylor, of Pennsylvania, were born in Ireland; John Witherspoon and James Wilson, of Pennsylvania, were born in Scotland, and Francis Lewis, of New York, was born in Wales. If we could have been in Independence Hall on those warm days of June and July, 1776, we should have seen half a dozen men or more who stood above their compeers in the part they took and the notice that was accorded them. First of all there was the President, John Hancock, of Massachusetts, who sat in a large high-back chair, behind the heavy mahogany table, and the great silver inkstand—a middle-sized, courtly looking man, with a ruddy face, which gave him the name of 'Rosy John' among his Tory enemies—and dressed in black velvet breeches and a scarlet coat with a great deal of gold embroidery about it. Mr. Hancock was favored by being one of the three men, with Samuel Adams and Benjamin Franklin, excluded by the King of Great Britain from the general pardon which was offered the American people if they would lay aside their arms. He had a princely fortune, and expended liberally of his means in the cause of freedom. He remained President of Congress till October, 1777, when he resigned in consequence of ill health. In 1780 he was elected the first Governor of Massachusetts, and was annually elected to that office, excepting an interval of two years when he refused to serve, until the year of his death, which occurred in 1793, when he was 55 years old. After the President, the most noticeable members were the five men who constituted the committee appointed to prepare the Declaration. They were Thomas Jefferson, of Virginia; John Adams, of Massachusetts; Benjamin Franklin, Roger Sherman and Robert R. Livingston, of New York. Thomas Jefferson was one of the youngest of the signers. At the time he drafted the immortal Declaration he was only 32 years old. He had the best classical education of any public man of his day, and was probably the best fitted for this particular work. As a composition the Declaration is Mr. Jefferson's. It is the production of his mind, and the high honor of it belongs to him clearly and absolutely. Jefferson's personal appearance was prepossessing and commanding. He was very tall and rather large boned, with light blue eyes and sandy hair. At a later day he was noted for his republican simplicity of dress, but at this time he was one of the finest dressed gentlemen in the colonies. In his long-waisted white cloth coat, scarlet vest and breeches and white silk hose, Thomas Jefferson must have been one of the most striking figures of that assembly. With his subsequent career all of our readers are familiar. Suffice it to say that before he was President he had been repeatedly Governor of Virginia, Commissioner and Minister to France, Secretary of State and Vice-President. He died on July 4, 1826. Of his colleagues Dr. Franklin was, beyond all others, the most celebrated. He had won European fame on account of his philosophical and scientific investigation. His superior attainments, his reputation and his venerable age, made him one of the most influential members of Congress. In stature Franklin was above the middle size and of full flesh. His long buff coat and embroidered silk vest were almost as familiar to his contemporaries as was his serene, benevolent face. For several years after the declaration of independence Dr. Franklin did excellent service for his country as Commissioner to France, Governor of Pennsylvania, and delegate to the Constitutional Convention. He withdrew from public life in 1789, and died the following year at his home in Philadelphia. John Adams, who was second on the committee, was one of the most prominent of the fathers of '76. Short in stature, pompous in manner, choleric, always puffing and blowing, his abilities atoned for a host of faults, and won him the highest gifts in the hands of his countrymen. While Jefferson was the author of the Declaration itself, John Adams was its great supporter on the floor of Congress. This was the testimony of Jefferson himself, who termed him 'our collossus in debate.' Adams afterwards represented the United States at the Hague and at the Court of St. James. He was Vice-President two terms and President for one, at the close of which he retired to private life. He died the same day with Jefferson, aged 81 years. Roger Sherman began life as a shoemaker. It is recorded of him that he early evinced an uncommon thirst for knowledge, and was wont, even while at work in his seat, to have a book open before him, upon which he would employ every moment not necessarily devoted to the duties of his calling. He was 55 years old when he signed the Declaration, and he lived to be a Representative to the National Congress, delegate to the Constitutional Convention, and Senator of the United States. He was a man of great natural sagacity, unbending integrity and force of character. He died at New Haven in 1793. Less is generally known of Robert R. Livingston than of many really less able men. A member of the great patroon family of the Livingstons, his ability and influential connections secured for him, before he was 30 years old, the appointment of delegate to the second Continental Congress. His influence in that body was second to none. The fact that the representative of the most powerful family in the colonies, a man who had everything to lose and little to gain from a successful revolution, gave his hearty approval to so radical a measure, won for that act the votes of members whom the graceful pen of Jefferson or the eloquent speech of Adams could not influence. Livingston subsequently became the first Chancellor of the State of New York, and as such he gave the oath of office to President Washington. He was a delegate to the convention that ratified the Constitution, and served as Minister to France under Jefferson. He was the great patron of Robert Fulton, and the first steamboat on the Hudson was named after his country estate, the Clermont. He died in 1813. One other individual must be named without whom there might not have been a Declaration at all. This is Richard Henry Lee, of Virginia. He it was who started the ball a-rolling on the 7th of June, 1776, by the following resolution:

'That these united colonies are, and of right ought to be, free and independent States; that they are absolved from all allegiance to the British crown, and that all political connection between them and the State of Great Britain is and ought to be totally dissolved.' As the mover of the original resolution for independence, it would, according to parliamentary usage, have devolved upon Mr. Lee to have been appointed chairman of the committee selected to prepare a declaration, and, as chairman, to have furnished that important document. Mr. Lee, however, was called away by illness in his family, and in his absence Mr. Jefferson was elected to that honor, by whom it was drawn up with singular energy of style and argument. Mr. Lee subsequently served in several Congresses, and later was elected the first Senator from Virginia. He died in 1794, aged 62 years."

EARTH GERMS.

THE PREVALENCE OF MICROBES IN THE SOIL.

Much has been written about the microbes in the air, in water, in the human system. Less than they deserve has been said of the organisms which people another element not less important, the soil. Does the soil contain micro-organisms? The answer is not doubtful. The smallest quantity of earth put in water reveals, through the microscope, besides the organic and mineral matter a mass of beings more or less complex, moving more or less rapidly. A German author, Mr. Reimers, has calculated that every cubic centimetre of earth may contain several million germs. Among these microbes some have not been studied, and the part they play in the economy of life is not known to us, while certain others have functions which have been well determined. The experiments of Messrs. Dehérain and Maquenne have clearly revealed butyric fermentation caused by microbes in the soil. Besides the microbes provoking this sort of fermentation there exist also in the soil pathogenous microbes, which may be very dangerous under certain circumstances. In the first rank of these microscopic but maleficent beings must be cited the germs of carbuncle, of septicæmia, of tetanus, and of typhoid fever. Carbuncle, the etiology of which has been studied so thoroughly by Mr. Pasteur and his co-workers, Messrs. Chamberland and Roux, is one of the most terrible maladies which can attack cattle and sometimes even men. Nowadays, thanks to labors of the *savans* whom we have just named, this malady has become quite rare, and tends more and more to disappear. For a long time it has been known that carbuncle was due to a particular microbe, but it was not known how it could be propagated. Mr. Pasteur has demonstrated that this propagation was due, in part at least, to the longevity of the germs. Thus it is that if you bury the dead body of an animal which has died of carbuncle in a ditch one or two metres deep, and cover it with earth, the carbuncle bacteria will be found in the neighboring soil several years after the interment. We can understand then that cattle put to graze on this land, or fed by provender from it, can contract the disease. So when the cause of this malady was unknown, superstitious country people called these places "cursed fields." It may excite astonishment that the earth is such a powerful filter, allowing germs to rise to the surface of the soil. Mr. Pasteur has shown that this action is due to earth worms, which are thus the vehicle of carbuncular ferment. In fact, the bacteria of carbuncle are found in the little cylinders of fine earth which the worms bring to the surface of the soil, and which rain lays flat. Great care, then, should be used not to inter animals which have died of carbuncle in a soil on which sheep are expected to graze, or from which it is intended to harvest food for cattle. In order to avoid the propagation of germs, while getting rid of the dead bodies of animals which have died of carbuncle, they should be interred in ground which is either sandy or calcareous, which has little moisture, and in which earth worms cannot live. A better way, however, as Mr. Aimé Girard has pointed out, is to treat the dead body of the animal with sulphuric acid, which shortly turns it into a black pulp, which can be mixed with manure, as, for example, with phosphates, to be spread over the surface of the soil. Cultivated land contains, besides the microbe of septicæmia of Mr. Pasteur, the bacillus of tetanus of Mr. Nicolaïer. Mr. Verneuil has proved that inoculations made with this poisonous earth develop among animals the two terrible maladies of gangrenous septicæmia and tetanus. Mr. Macé has shown, in an analogous way, that earth contains the bacillus of typhus fever. The fact that the soil contains pathogenous microbes is utilized by the savages of the New Hebrides to poison their arrows. As we have seen, earth contains a great number of microscopic beings, of which some are dangerous and many are imperfectly known. Now, when earth is dried and gives to the wind a great quantity of dust, it may be asked if, among this dried earth thus suspended in the atmosphere, there are not germs capable of producing maladies like those we have mentioned. Although this question has not yet been studied, it would appear, from several examples, that these germs may become nearly inoffensive. It is known that a great quantity of water from the sewers of Paris is poured on the peninsula of Gennevilliers, which is thus transformed into a fertile garden. It is certain that the sewer water contains an incalculable number of microbes, of which many are the germs of terrible maladies, such as cholera and typhoid fever. An immense quantity of this sewer water is poured on the soil of Gennevilliers, and it may be imagined what an enormous number of micro-organisms there must be on the surface of the land. If the fears that may be entertained of the propagation of maladies were well founded, there would be a marked increase of mortality among the inhabitants of the land of Gennevilliers; but the sod of this peninsula has been treated with sewer water for the last twenty years, and there has been no increase in the number of deaths. Thus, while the question is far from being settled, it may be believed that the microbes, when deposited on the surface of the soil, and then carried away in a dry state by the wind, are not dangeous. Besides the beings I have mentioned, earth contains other bacteria, of which the function is quite different, and which play a very important part, from the point of view of vegetable physiology. Mr. Berthelot has demonstrated by a great number of experiments that earth can fix the atmospheric azote, through the intervention of certain micro-organisms. Some time since Mr. Breal published a study on the bacteria of the *leguminosæ* which have this property of assimilating the azote of the air. Finally, the soil contains the nitre-making microbe, in regard to which some new and very interesting experiments have recently been made.

TRAINING FOR THE THRONE.

HOW THE EMPEROR OF GERMANY WAS TAUGHT MILITARY SCIENCE.

The athletic development of Emperor William II. of Germany began in his seventh year. Two years later six-year-old Prince Henry joined him in his exercise. The two young Hohenzollerns received together all sorts of drill in clubs, dumb bells, apparatus turning, fencing and swimming from 1868 till 1875. The indoor and out-door gymnasiums were in the park of the New Palace in Potsdam. Three ships' masts were erected nearby, and to them were made fast all the usual rigging, after the model of the royal ship Hela at Danzig. The ground was ploughed round these masts, and nets were stretched so as to moderate the dangers of princely falls. Here the present Emperor received, under a naval officer, daily drill in the management of a ship's running and standing gear. Between the mock ship and the open place for gymnastic games there was a target for practice in sharpshooting, and, a few yards from it a bit of greensward for fencing bouts. A wide piece of undulating land, with a little underbrush and a few trees on it, was used exclusively for object lessons in the construction of breastworks, trenches, and for the illustration of other problems of military fortification. Prince William excelled in fencing and swimming. After two years of instruction he could swim for an hour without resting. On the small field of battle near the New Palace he and his royal companion and several cadets constructed a little wooden fortress, surrounded by deep ditches and armed with tiny cannon which fired blank cartridges. Throughout the summer this fortress was stormed daily under the leadership of the little Prince, was forced to silence, and the French flag on its walls was torn down by small royal hands and was replaced with the Prussian colors. Upon the withdrawing of the garrison Prince William led his cadets in pursuit through the length and breadth of the park. He went into camp with them at the end of every hour's march, helped them set up tents, build fires, and cook coffee and potatoes over the coals. Pickets were stationed, scouts were sent out, and sometimes earthworks were thrown up. At five o'clock in the afternoon Castle Lindstedt was stormed, and all sorts of sweets were carried off as the booty of the conquerors. Finally the little army of cadets, led by Prince William, and the fleeing garrison, under Prince Henry, arranged an armistice to last till the following day, and all the young soldiers marched back to the New Palace to be reviewed by the Crown Prince and Crown Princess.

SACCHARIN TABOOED.—The Russian Medical Council follows the example set by Italy and France and prohibits the use of saccharin in articles of food, and drink.

CONTAGION SCREEN.—In the children's hospital in Paris, Dr. Grancher, in order to prevent house infection, surrounds each bed containing a case suspected of being contagious with a screen to prevent personal contact. He assumes that the danger of infection through the air is not great.

OBVIOUS MORAL.—There is a man in our town, and he is wondrous wise; whene'er he writes the printer man, he dotteth all his i's. And when he's dotted all of them, with great sang froid and ease, he punctuates each paragraph, and crosses all his t's. Upon one side alone he writes, and never rolls his leaves; and from the man of ink a smile, and mark "insert" receives. And when a question he doth ask (taught wisely he had been), he doth the good penny stamp, for postage back, put in.

IMPORTANT DISTINCTION.—Sanitarium and sanitorium are words often used synonymously, but really of different, though allied meanings. Sanitarium is derived from the Latin *sanitas*, healthy, and means a place of health, a health retreat, a spot where correct sanitary conditions prevail. Sanitorium is derived from the low or late Latin sanitorius, which in turn comes from the Latin *sano*, *sanare*, to heal, and means a place of healing, a curative retreat, a spot where active health-restoring conditions prevail. The former, in brief, is hygienic or prophylactic; the latter therapeutic. The same distinction is to be observed between sanitary and sanitory.

FRENCH SYSTEM.—The town of Carcassone in France was recently condemned by the Civil Tribunal to pay indemnities of 100 francs and 50 francs to two of its inhabitants in respect of damages they had sustained by illness caused by eating mushrooms purchased in the public market. The grounds of the decision were that persons buying mushrooms had a right to expect that their innocuous quality had been verified by the inspector of markets before they were publicly exposed for sale, and that this official having neglected his duty, the municipality was liable for the consequences of such neglect. They certainly do manage some things better in France than in some other countries, where *caveat emptor* is the "custom of the trade" in nearly everything relating to food and drink. —*British Medical Journal.*

ITALIAN COOKERY.

SOME OF THE FAMOUS DISHES OF SUNNY ITALY.

On the general principle that culinary tradition is about the most unchanging of all our inheritances, we should expect to find Italian kitchen methods of to-day to have a general resemblance to those described for us by the classic writers of Rome. There is a resemblance, but it is not very close, and for this reason, probably, these old writers were denouncing the epicurian excesses of voluptuaries, and not describing the frugal meals of plain men. Juvenal, Horace, and Martial were satirists, not editors of cookery books, and the "dish of flamingoes' tongues" alluded to by Martial, the "livers of capons stewed in milk," as described by Pliny, were certainly never national dishes, not even such as frequently graced the board of the modest burgess. Nevertheless, the Italian of to-day lives upon many of the dishes that his Roman ancestor cooked and ate; and what is curious, as showing the conservatism of the affairs of the kitchen and the dining-room, the ordering of a set dinner itself, the sequence of courses, the arrangement of the *menu*, in short, derives through the mediæval Italian direct from classical times, and is now adopted throughout the civilized world. The Romans used the phrase—*Ab ovo usque ad mala*—from preliminary *hors d'œuvre* to dessert—to signify a complete dinner, and the interval was filled with fish, *entrees*, roast meats, game, and sweet things, in the order in which the civilized dinners are served. The Italians of to-day inherit from their ancestors the use as food of olives pickled, raisins of the sun, almond cakes, hard cheeses, open tarts (*scriblitae*), becaficos, mushrooms of many kinds, sausages, and oysters, all of which they have made common to the rest of the world. The Romans committed what we must consider the enormity of eating dormice, and even of esteeming them highly; but the dormouse of Italy is not the tiny beast of our English woods, but a larger and fatter creature of a different species, and in some parts of Italy it is cooked and eaten to this day, though I do not know that the fashion extends beyond the Peninsula. If we have nothing in the shape of a classical recipe book, but only inventories of ancient Roman dishes, and *catalogues raisonnees*, so to say, of great feasts, we have other grounds for knowing how little after all modern Italians have departed from the cooking methods of their forefathers. In our museums are to be found the very frying-pans, spits, saucepans, baking tins, cullenders, table knives and spoons used in Italy 1900 years ago. They are incidental with those we still use, so that we may safely conjecture, without other grounds to go upon, that the dishes they resulted in were not far different from those we eat to-day. In the so-called house of Pansa at Pompeii is to be seen a cooking-stove, for stews, of quite modern pattern. On the hot plate in front of it lie, just as the Pompeiian cooks left them, a kitchen knife of the ordinary sort and size, and one of those frying pans with divisions, for poaching eggs, which modern conceit supposes he has invented within a generation. Italian cookery, as shown in the following recipes, is, in the main, the ancient Roman cookery, with such reforms and additions as 1900 years have taught one of the most ingenious people in the world. They have invented macaroni and spaghetti: and polenta has come to them with the discovery of maize. Modern Italians still make the characteristic sweet-sour sauce (*agro-dolce*) in which their forefathers stewed the haunches of the wild boar. On the other hand, they have lost the secret of the most famous sauce of antiquity, the *Garum*, and though, on the revival of ancient learning, Rabelais boasted that he had rediscovered the recipe for making this celebrated condiment, his recipe is no more than a literary one, and has not found its way into practical cookery books.

ITALIAN DISHES.

MINESTRONE (SOUP).—Take every kind of vegetable, cabbage, carrots, turnips, spinach, etc, wash them and cut them in pieces about the size of a nut. Pound together a clove of garlic, some parsley, and some leaves of thyme, until they make a paste; add salt and pepper to this, mix it with the vegetables, and put all into a saucepan with sufficient stock or water for the quantity of soup required. When half-cooked, add some macaroni and a good quantity of Parmesan cheese. If preferred, the cheese can be served separately.

ZUPPA AL BRODO DI PESCE (FISH BROTH).—Fry lightly in a saucepan with butter and oil in equal parts, an onion, a carrot, some celery, and a little parsley, all well pounded. Put in this mixture any chosen fish, suitable for making a broth, adding salt to taste. Let the fish brown a little, then put in some tomatoes cut in pieces, some dried mushrooms cut up very fine, and by degrees pour in as much boiling water as the quantity of soup required. When the fish is thoroughly cooked and almost in shreds, take the saucepan off the fire and let it cool a little; then strain the broth and pass through a sieve the remains of fish, etc., in the saucepan; put this into the broth already strained and put it on the fire to boil another half hour. Add some toasted bread cut in dice, and serve grated Parmesan cheese with the soup.

POLLO CON FORMAGGIO (FOWL WITH CHEESE).—Truss and flatten a young chicken and slightly cook it in a saucepan with some butter, and then moisten it with a wineglassful of light white wine and the same quantity of stock or broth; add a bunch of mixed herbs, salt and pepper, and cook it for an hour over a very slow fire without letting it boil. Then take the chicken out of the saucepan and thicken the sauce with a piece of butter the size of a walnut, worked up with flour. Take the hot dish on which the chicken is to be served and pour on it a portion of the sauce and mix with it a good spoonful of grated cheese. Dish up the chicken and pour over it the rest of the sauce with the same quantity of cheese; then put it in the oven till it is slightly browned and the sauce is completely absorbed.

FRITTURA MISTA (MIXED FRY).—Daily in Italy a dish is served as an *entree* composed of various meats, fish, and vegetables delicately fried. Calf's and chicken's livers cut in thin small slices are the usual basis of the fry, to which are added neatly trimmed veal cutlets, brains, mussels, oysters, the yolks of hard-boiled eggs, artichokes, cauliflowers, and any other vegetable that is fancied. Prepare these various ingredients by blanching the brains, washing the vegetables, and cutting them in neat, not too small, pieces. Then dip the brains and the veal cutlets into the yolk of an egg, well beaten, and again into fine bread-crumbs seasoned with pepper and salt, ready for frying. The slices of liver, fish, vegetables, and other ingredients must be simply dipped in flour already seasoned, and then all must be fried in boiling fat, putting in first the veal cutlets and those ingredients which take longest to cook. Carefully drain from fat the pieces of meat, etc., arranging them on a hot dish, the cutlets or larger pieces in the centre. Serve very hot.

POMI DI TERRA ALL' ITALIANA (POTATO BALLS WITH CHEESE).—Boil some potatoes in salted water; when quite cooked, after removing the skins, throw them into a pan and cover them with grated Parmesan cheese, stirring all well together. Form the mixture into balls about the size of potatoes and dip them into white of egg, and then into flour. Fry them until they are crisp and of a pale gold color, drain them carefully from fat, sprinkle them with a little salt, and serve quite hot.

FUNGHI CON ERBE FINE (MUSHROOMS WITH FINE HERBS).—Cut some large, fresh mushrooms in half, wash and drain them, then place them for two hours in oil, salt, pepper and a little garlic. Fry them in butter, with parsley and chopped onions. Put them in a fire-proof dish, moisten them with a little oil, sprinkle them with bread-crumbs, and heat them over a gentle fire. When quite hot squeeze a little lemon juice over them and serve.

RAVIOLI.—Prepare a paste with flour, eggs, and a pinch of salt. Have ready some forcemeat made from cooked fish, meat or poultry, mixed with fine herbs and lemon peel chopped very fine. Roll the paste until it is as thin as parchment, cut into circular pieces three or four inches in diameter; place on each a portion of the forcemeat, then double the paste and pinch the edges together. Place the Ravioli in a deep fire-proof dish, pour some stock over them, and powder them with grated Parmesan cheese. Put them in the oven for twenty or thirty minutes, and serve them very hot in the dish in which they have been baked.

RISOTTO A LA MILANAISE.—For six persons, take half a pound of rice, well washed and perfectly dried. Put it into a stewpan with half a pint of good stock and a quarter pound of butter, a little pepper and a little salt. Let it cook gently, stirring it constantly with a wooden spoon until it is just tender, leaving each grain whole. The stock and butter should be absorbed by the rice. Add a little powdered saffron while the rice is stewing, and just before it is quite cooked add about two tablespoonfuls of grated Parmesan cheese. If preferred, a teacupful of fresh tomato sauce can be added instead of the saffron. It must be served very hot.

RISO E PISELLI (RICE AND GREEN PEAS).—For six persons, take half a pound of Italian rice, well washed and dried. Put it into a stewpan with a quarter of a pound of butter, stirring it until it is of a bright golden color, but great care must be taken not to burn it. Then add a teacupful of good stock with half a pint of fresh green peas, stirring the whole together till the rice and peas are tender; add salt and pepper to taste, and serve hot. The rice must always be in grains.

TAGLIATELLI.—Make a paste of flour, water, and one or two eggs, according to the quantity required. When the paste is thoroughly well kneaded, roll it to the thinness of a wafer biscuit, and cut it into long strips a quarter of an inch wide, or into fancy shapes with a paste-cutter. Dress these strips in the same way as macaroni, throwing them first into boiling water and letting them boil for some minutes. Take them out and put them into cold water, and drain them carefully on a sieve. Then place on a dish some butter and some grated Parmesan or Gruyère cheese, a layer of *Tagliatelli* seasoned with pepper, another layer of butter and cheese, and so on till all is used. Pour over the whole a cupful of rich cream, then add a layer of cheese, and cook in a moderate oven.

MACCHERONI (MACARONI).—Put a bunch of sweet herbs, half an onion, two cloves, three ounces of lean ham, one pound of lean beef, half a chicken, and a truffle into a stewpan with a good piece of butter, and brown them to the color of a hazel-nut; then add a quart of water, and boil down till reduced to about a tumbler of stock. Remove the meat and skim all the fat off. Boil in water one pound of macaroni, drain it well, and throw it into the saucepan containing the stock, with six ounces of butter and one ounce of Parmesan cheese. Stir well over the fire and serve very hot.

POLENTA CON CREMA (MAIZE PORRIDGE WITH CREAM).—Put into a rather large saucepan filled with boiling water, slightly salted, about two pounds of Indian corn flour, and stir it continually with a porridge stick. As soon as the *Polenta* is cooked, which may be known by the holes formed in the middle by the flour in boiling, turn it from the saucepan on to a board, where it must be allowed to cool. Now take another saucepan, which must be lightly buttered all over inside and sprinkled with bread-crumbs or flour. Raise the *Polenta* from the board very delicately with a large knife and put it into the saucepan, covering the bottom and sides. The remainder must be cut in thin, fine slices, of which layers are formed on the paste in the saucepan alternately with butter and grated Gruyère cheese, first pouring over each layer of *Polenta*

some thick cream. When it is all used, place it in a moderate oven for half an hour, when it will be ready for serving. Turn it very gently from the saucepan on to a hot dish, keeping the crust underneath. This is an excellent dish.

ZABAJONE OR SABAIONE.—This is a frothy mixture composed of wine, yolks of eggs, and sugar, thickened on the fire. The wine generally used is old Cyprus or Madeira; or two different kinds, one sweet and the other dry, may be mixed together, such as Malaga and Marsala. The ingredients should be in the following proportions: The yolks of three eggs to each person, a good teaspoonful of sugar to every egg, and as much wine as the shells of the eggs will contain. Beat up the eggs and sugar with a little powdered cinnamon, add the wine, and put the mixture in a saucepan on a brisk fire. Stir it without intermission until it has thickened, but do not allow it to boil. Serve hot, either in custard cups, when it may be eaten with cake or sweet biscuit, or it is excellent as sauce over any light pudding.

A PARISIAN DINNER.

ANOTHER PLACE THAT NEEDS A PURE FOOD "HEALTHERY."

According to *Le Cosmos* the following is the agreeable *menu* of a Parisian dinner:

As aperitive, a vermouth, which is rendered agreeable by the addition of sulphuric acid.

The diner then attacks his potage of tapioca—made of potato starch to which copper has been added.

His butter is made of calf's fat colored with lead.

His roast, of inferior quality, has been improved with saltpetre; he discovers a few truffles made of pressed clay.

The vinegar of the salad is seasoned with vitriol.

The peas—a little too green—taste of the copper which has given them their color.

Dessert: A chocolate cream; the chocolate is made of glucose, red oxide of mercury and red ochre.

For coffee he is given a mixture made of horse-liver roasted in the oven, black walnut sawdust, and caramel.

His small glass of kirschwasser, which terminates the dinner, contains as high as twenty-two centigrammes of prussic acid to the litre.

After such a meal the Parisian has a terrible thirst; he wishes to drink beer, and he drinks it. It is a decoction of poppy-heads, elder, belladonna, datura stramonium, soda, tan-bark and picric acid!

DOMESTIC DIETETICS.

SPECIALLY PREPARED FROM PRACTICAL TESTS, FOR THE LADY READERS OF THE "AMERICAN ANALYST."

SEASONABLE FOOD.

July.

MEAT.—Beef, lamb, mutton, ham, kidneys, liver, sausage, veal.

GAME AND POULTRY.—Pigeon, chicken, duck.

FISH.—Anchovy, bass, bluefish, blackfish, cod, eels, clams, flounder, haddock, halibut, herring, lobsters, mackerel, mussels, perch, porgie, prawn, salmon, shad, turtle, trout, sturgeon, whiting, weak-fish.

VEGETABLES. — Beans, cucumbers, carrots, cauliflower, egg-plant, lettuce, onions, parsley, parsnips, potatoes, shallots, spinach, turnips, radish, rhubarb, corn, beets.

FRUITS.—Cherries, strawberries, raspberries, huckleberries, melons, gooseberries, blackberries, peaches, pears, tamarinds, bananas, pineapples.

PRACTICAL RECIPES.

PUREE OF BRUSSELS SPROUTS.—Pick over carefully two quarts of sprouts, wash them thoroughly, and plunge them into a liberal quantity of boiling water slightly salted; boil twenty minutes, drain, and force them through a colander; then rub them through a sieve; return to the range and add two quarts of soup stock. Wet half a teaspoonful of flour in a little cold milk and whisk it into the soup; add two saltspoonfuls of salt gradually, and taste the soup while adding it. A dash of cayenne is preferable to other peppers. Scald a pint of rich cream, and whisk it into the soup; taste for seasoning, and serve with snippets of bread.

ALMOND CAKE.—Beat until light one cupful of butter and two and one-quarter cupfuls of sugar, add two and one quarter cupfuls of milk, then four and one-half cupfuls of lightly sifted flour; add the well beaten yolks of four eggs and another half cupful of flour in which four teaspoonfuls of baking powder have been mixed. Flavor with bitter almond and beat the whites of the four eggs in the last thing.

SPINACH GREEN FOR COLORING.—Wash a peck of spinach in several waters, drain it quite dry and chop it fine, then pound it in a mortar until reduced to pulp, put this in the centre of a strong sheer towel, and with an assistant twist the ends of the towel in opposite directions. Allow the juice to drip into a porcelain lined dish. To each pint of juice add a tablespoonful of fine sugar. Set the dish in a pan of hot water to evaporate one-third and set aside to cool, then bottle and seal.

BAKED CRABS.—Put one teacupful of vinegar in a quart of water and bring it to the boil, then put in the crabs and steam them for half an hour. Let them get cold, pick out the meat, carefully rejecting the entrails. Butter a baking dish and put a layer of the meat in it; over this sprinkle a layer of bread crumbs and some bits of butter and pepper and salt, then some more crab meat and so on until the dish is full. Sprinkle on top some crumbs, pour over all a cupful of rich cream, add a final sprinkling of crumbs, a few bits of butter, and bake a delicate brown. Serve very hot. Canned crab meat may be used when fresh crabs cannot be had.

VANILLA CUSTARD ICE CREAM.—Put one quart of sweet milk, two vanilla beans and one-half pound of powdered sugar in a bright saucepan. Place on the fire and bring it the boiling point, then pour it upon the yolks of twelve eggs, slightly beaten; stir well together, replace it on the fire and keep stirring until the custard begins to thicken. A large spoonful of pure vanilla extract may be used instead of the beans. When the custard mixture is finished and cold, add to it half a pint of double cream and a glass of brandy. Mix, freeze and mould.

APPLE SAGO PUDDING.—Soak a cupful of sago in enough water to cover it, over night. In the morning put the sago into a saucepan, set it in a pan of water, pour a pint of hot water over it and let it cook very slowly until the sago is clear; do not stir. If all the water soaks up add a little more to cook it properly. Pare and core six fine apples, put them into a pan with a tablespoonful of sugar to each apple and a cupful of water. Cook slowly, and when done pour the sago over them when they are very cold. Serve with sugar and cream.

BREAD CHEMISTRY.

EXPLANATION OF THE PHENOMENA OF FERMENTATION.

The art of bread making is one which is subject to this peculiarity, that the conditions of its manufacture are never stationary, but vary every day in the year, and every hour in the day. Notwithstanding this, the laws which govern its processes never vary; they are as unchangeable as the propositions of geometry, as the multiplication table. The phenomena of nature do not move at random. There is no such thing as chance. If our bread be faulty, if we are puzzled, it only shows that some law has come into play which we have failed to recognize, so if we desire to escape failure we must study the laws. And this brings us face to face with chemistry. But a wide experience compels me to own that practical men do not always take kindly to it. And no wonder; for it is only within a few years past that chemistry has had anything to say for itself. Till lately it was as much in the dark as we were ourselves. The common feeling concerning chemistry is that for us it is impracticable. Its language is abstruse, its symbols appaling. We cannot spare the time for such mysteries, even if we had the brains. But, do our needs require this great expenditure of time and exercise of brain power? All we need lies within so easy reach that a man who could neither read nor write may grasp it. Chemistry is a wide subject, but we are not obliged to wade through the whole curriculum. There is the chemistry of medicine, of agriculture, of photography, of the gasworks, the dyeworks, and a hundred others—each dealing with a hundred different substances, while our chemistry, with scarcely more than two, is simplicity itself. We have wheaten flour to convert into bread, and we use yeast to act on it. Salt and water and the process of baking are but minor details, entailing no anxiety. The whole trouble lies in a nutshell, and centres in the due decomposition of the flour previous to baking: Even this, when the yeast is suitable, gives no anxiety. But what a depth of meaning lies in the words, "When the yeast is suitable?" We can all judge a sample of flour with sufficient closeness. We can all mix a sponge, make a dough, heat and temper an oven, and bake a batch of bread; but it is not enough now to know how. The old easy-going days of bread making are past, and if we do not also know why, we shall soon get left behind by those who do. To know this we must have a clear conception of the phenomena of fermentation. How simple the theory of these phenomena is I now propose to explain. Let us assume first that our flour is of suitable quality. We want to produce in it a certain degree of decomposition. We all know that yeast effects this, but yeast, being a plant, is bound to share the vicissitudes of plant life. It may or may not be healthy; it may or may not be of the right species; and, above all, it may or may not be free from admixture with plants different from itself. When we mix yeast with flour we are sowing a crop, and should act accordingly. If we were about to sow a crop of wheat, we should not think of sowing a mixture of red and white wheats, or of wheat mixed with oats or hemp seed. How often do we do this with yeast? I can give you an idea. Every time we have sour bread, every time we have ropy bread, every time we have a flinty crust, almost every time our yeast is faulty. In order to explain this subject more fully, allow me to take an illustration from the growth of common plants around us. Let us take a grain of wheat, a grain of oats, a grain of barley, a pea, a turnip seed, a seed of hemlock, and so on, till we have nineteen varieties of seeds suitable for our purpose. Now let us have a quantity of clay sifted and turned over, so as to be perfectly homogeneous and filled up into twenty flower-pots. The contents of these pots we now assume to be identical throughout. Now let us sow our nineteen seeds in nineteen pots, leaving one pot untouched, and what will be the result? Supposing all to grow and mature, we shall have nineteen crops, all different in analysis. We may set these crops aside now, having no further use for them, and turn our attention to the pots of clay. The question then is, are the contents of these pots identical as at the beginning? No; each crop has taken its own peculiar nourishment from the clay, so that we have nineteen varieties of clay along with the original one. Further, supposing we could eat clay, we should find twenty different foods, twenty different flavors, twenty different degrees of nutritious value. And so it is with the ferments—as they vary, so will the bread vary; whether it be sweet or sour, pink, ropy, or flinty, the ferments are at the bottom of it all. Yeast also differs in itself; that is, there are different species of it as there are different kinds of grapes or of roses; it is subject to ailments, old age, etc., but it

never will nor can produce sour bread; that is the function of other organisms. Electrical disturbances, such as thunder storms, are held responsible for injuries, and the great electrical earth currents, which are continually passing under our feet, are among the possibilities. But these considerations form no part of my idea of practical chemistry; what we want is to know a little about the functions of yeast and its enemies, and to judge and distinguish them. Even at the risk of over-repetition I cannot avoid adding that bread cannot in itself turn sour. When sourness shows we see the work of acid producing germs, originally present in the dough, and so tenacious of life as to survive the process of baking. For this purpose the microscope is our sheet anchor; but to buy one is like buying a piano, a bicycle or a pair of skates—its use can neither be learned nor continued without some expenditure of time.—*Irish Provision Merchant.*

VEGETARIANISM.

THE PRINCIPLE FALLACIOUS, AND CONTRARY TO REASON.

The London *Popular Medical Monthly* for July says, on the above subject: "We do not go so far as to call vegetarians 'barbarians,' but we think vegetarianism, as a system, is a fallacy. Something can be said for every *ism;* but when the position taken up by the opponents of vegetarianism is not a purely animal as against a purely vegetable diet—beef *versus* beans (taking those two articles of diet as good representatives of each system)—but a mixed diet, or beef *plus* beans *versus* beans and other vegetables, we, from a medical point of view, fail to see the good of their society. It may be argued that many people eat too much animal food. That may be so, but when that is admitted it scarcely justifies, in matters of diet, the total abolition of that article. We would here point out that the tendency of medical science is rather to extend the use of an animal diet than to curtail it. To the question, Can health be sustained indefinitely upon a diet of lean meat and water without *any* farinaceous food at all? experience says yes, even if physiology should say no. A diet of lean meat is now being advocated for several purposes in practical medicine, as in obesity, dyspepsia, consumption, and in the absorption of new growths—tumors. In another page we give several examples of people who live almost entirely on animal food, and their experience is not to be overlooked. It may be remembered that, some years ago, at the Aquarium, were exhibited a family of savages who lived all their lives exclusively on lean meat, fish and water; they were cannibals from Terra del Fuego, belonging to the tribe of Onas, and consisted of five adults and two children. The man, aged thirty, took little exercise, and ate every twenty-four hours five pounds eight ounces of lean, cold, boiled horseflesh, two pounds raw fish, and one or two eggs and about four pints of water. In spite of this extraordinary diet there was nothing unusual about the man, regarding him from a medical point of view. Physiology has yet to explain cases like these. Another point not to be lost sight of in connection with this family: where they lived there is nearly always snow on the ground, and yet they reject fat from their diet and take no starchy food at all; they take little exercise, and spend a great portion of their time in sleep. We are not advocating a purely animal diet, only pointing out the fact that it is possible to live on such a diet, and to live in health. It does not go for much, on one side or on the other, that people can live on a purely vegetable or on a purely animal diet. The question rather is, What is the most conducive diet for health and for work—not for savages, but for us who live in England? Anatomy and physiology point to a mixed diet. This vegetarians deny. They say, for example, that the canine teeth in man are not long and projecting, as in the lion and and the dog. To this the obvious answer is: Men do not require to tear with their teeth the flesh from the bones, hence they are not developed for that purpose. As to the anatomy of the stomach, one cannot imagine anything more suited for the digestion of a mixed diet, as it neither resembles the carnivorous nor the herbivorous stomach, and, if it has any resemblance at all, it is a compound of the two classes of animals. A vegetable diet being more complicated and difficult to digest than a flesh diet, we find the digestive apparatus more developed in herbivorous than in carnivorous animals. The length of the intestinal canal is very marked in the former, and a portion of the large bowel attains great dimensions in order the better to assist in the extra digestive requirements. But what we deem more important than anatomy and physiology are the results of experience and daily observation. That a purely vegetable diet suits some people better than a mixed is nothing to the point; would it suit the masses of people better? Speaking for dwellers and workers in large towns, we say no. We are well acquainted with the results in Scotland of what vegetarians call a vegetable diet—oatmeal and milk. The Scotch ploughman develops a fine physique, and gets through his mechanical work on these. This he is enabled to do in consequence of the large amount of fresh air and out-door exercise he gets. Let the average Londoner try it, and in three months he would break down. Let the brain-worker try it, and he, too, would collapse. The diet, besides being chemically sufficient, must be palatable, in order to promote the flow of gastric juice, or to enable one to take enough for the requirements of the body, and it must be capable of being digested and assimilated by ordinary stomachs. For instance, to quote Prof. M. Foster's standard work on 'Physiology:' 'A chunk of cheese stands very high on, generally at the top of, a table of the nutritious value of articles of food drawn up on exclusively chemical principles, according to the units of energy present in a unit of the material; but it is very low down in a corresponding physiological table.

Buffalo Lithia Water, Spring No. 2, in Bright's Disease, Gout, Stone in the Bladder, and Diseases Generally of Uric Acid Diathesis, Etc., Etc.

DR. WM. A. HAMMOND, of Washington, D. C., Surgeon General U. S. Army (retired), Professor of Diseases of the Mind and Nervous System in the University of New York, etc.

"I have for some time made use of the BUFFALO LITHIA WATER in cases of AFFECTIONS of the NERVOUS SYSTEM, complicated with BRIGHT'S DISEASE OF THE KIDNEYS or with a GOUTY DIATHESIS. *The results have been eminently satisfactory.* Lithia has for many years *been a favorite with me in like cases, but the* BUFFALO WATER CERTAINLY ACTS BETTER THAN ANY EXTEMPORANEOUS SOLUTION of THE LITHIA SALTS, and is, moreover, better borne by the stomach. I also often prescribe it in those cases of CEREBRAL HYPERÆMIA resulting from OVER MENTAL WORK—in which the condition called NERVOUS DYSPEPSIA exists—*and generally with* MARKED BENEFIT."

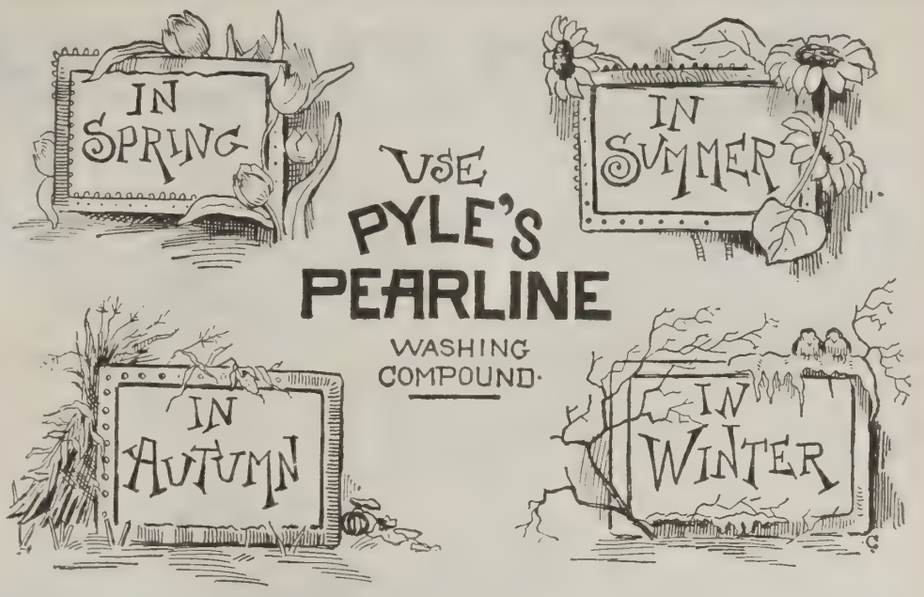
DR. WM. B. TOWLES, Professor of Anatomy and Materia Medica, in the Medical Department of the University of Virginia.

"BUFFALO LITHIA SPRINGS, No. 2, belongs to the ALKALINE or, *perhaps, to the* ALKALINE SALINE Class, *for it has proved far more efficacious in many diseased conditions than any of the simple* ALKALINE waters.

"*I feel no hesitancy whatever in saying that in* GOUT, RHEUMATIC GOUT, RHEUMATISM, STONE *in the* BLADDER, and in all diseases of URIC ACID DIATHESIS, *I know of no remedy at all comparable to it.*

"*Its effects are marked in causing a disappearance of* ALBUMEN *from the urine. In a* single case of BRIGHT'S DISEASE *of the* KIDNEYS, I witnessed *decided beneficial results from its use, and from its action in this case I should have great confidence in it as a remedy in certain stages of this disease.* In DYSPEPSIA, especially that form of it in which there *is an excessive production of* ACID *during the process of nutrition*, in some of the PECULIAR AFFECTIONS *of* WOMEN, notably in SUPPRESSION of the MENSES, and in CHRONIC MALARIAL POISONING, etc., I have found it highly efficacious."

DR. G. HALSTEAD BOYLAND, late Professor of Surgery, Baltimore Medical College, late Surgeon French Army (Decorated), Member Baltimore Academy of Medicine, Member of American Medical Association.



"In BRIGHT'S DISEASE of the KIDNEYS, ACUTE or CHRONIC, BUFFALO LITHIA WATER, Spring No. 2, is, in my experience, *without a rival*, whether in the PARENCHYMATOUS form or INTERSTITIAL NEPHRITIS. In cases in which the ALBUMEN in the URINE reached as high as 50 per cent., I have known it under a course of this water gradually diminish and finally disappear, at the same time other alarming symptoms were relieved and the sufferers restored to health.

"In STONE in the BLADDER of the RED LITHIC ACID and the WHITE PHOSPHATIC DEPOSIT, the SOLVENT power of this water is *unmistakable.*"

Water in cases of one dozen half gallon bottles, $5.00 f. o. b. here.

THOS. F. COODE, Proprietor, BUFFALO LITHIA SPRINGS, VA.

And, similarly, a dish of old peas has a very different physiological function from a plate of fresh meat, even when both contain the same amount of nitrogen.' Beasts of burden live on a purely vegetable diet and possess great strength; but man's highest end is not mechanical work. The races which are vegetarian in diet do not stand high in brain-power, nor are they noted for their strength or endurance. A vegetarian diet wants the *stimulus* and the sustaining power of an animal diet. Dr. Dundas Thompson tells of the effects of meat on some Indians, who were in the habit of having a vegetable diet only, feeling intoxicated after a good meal of flesh, showing it to be a true stimulant; even pigs become pugnacious when fed on meat. Who ever heard of such effects from a vegetable feast? Vegetarianism tends to produce fat; even dogs and cats get fatter on a vegetarian than on an animal diet. On the other hand, a flesh diet forms muscle, and not fat; hence, Banting and others forbid farinaceous food in obesity and in training. The experiments of Pettenkofer and Voit showed that an animal diet increased the absorption of oxygen by the lungs; this undoubtedly favors the disappearance of fat. An animal diet stimulates all the processes of the body; it is more satisfying and has greater staying power. An evidence of the low vital power induced by living on a vegetable diet is to be found in ulceration of the cornea, so common among Hindoos and others. A great deal of nonsense is talked and circulated in the leaflets issued by the Vegetarian Society. A much better case might be made out for vegetarianism than is to be found in any of the pamphlets the society circulates. Vegetarianism has some advantages in selected cases, and suits a few people as well, if not better, than a mixed diet. It has the advantage of cheapness. Here is a dinner we quote from one of their pamphlets: 'Dinner—total cost, 1s. 5d for six persons—Pea soup, potato pie, brown pudding.' The first two courses speak for themselves; the third course is composed of bread, apples, raisins, sugar and nutmeg. The weak part of this course lies in the centre dish. We admire the appetite of the man or woman who can devour a pie made of potatoes and onions! It must be an appetite begotten of semi-starvation."

Beware Peddlers and some unscrupulous grocers will tell you, "this is as good as" or "the same as Pearline." IT'S FALSE—Pearline is never peddled, and if your grocer sends you something in place of Pearline, do the honest thing—*send it back.* 241 JAMES PYLE, New York.

Make two cakes, one with Cleveland's baking powder; the second with any other.

Note the difference.

The Cleveland cake is fine grained, keeps its natural flavor and moisture; "the other" is coarse grained, as if the sugar was too coarse, soon dries out and becomes husky.

Cleveland's leavens best because its strength is produced by cream of tartar and soda only, not by ammonia or alum.

A CHURCH TONTINE.—A novel plan for extinguishing a church debt has been hit upon in Melbourne. The church committee—or vestry, as the case may be—divide the total debt among themselves and each man insures his life for the amount that falls to his share. The policies are transferred to the church, and the annual payments on them are made out of the collections. Then, of course, as the members of commit- "drop off," the sums insured on their lives drop in, and later, when the last committeeman is dead, the last instalment of the church debt will be paid. The plan has the merit—if merit it be—of throwing the whole responsibility for the continuance of the indebtedness upon Providence.

A SPIDER'S PERFIDY.—Some men who were trying to keep cool in a stable at Yorkville yesterday afternoon had an opportunity to witness the fidelity of a little spider and the rascally perfidy of a big one. Incidentally, also, they saw the death of a large horse-fly. The fly had entangled himself in the big spider's web, and his struggles threatened to tear the structure to pieces. The builder of the trap saw the danger, but he dared not attack his powerful captive alone. Swiftly he ran down the wall, and in a few moments returned, followed by a small spider, whose unpretentious web was near the ground. Then the big spider seized the fly from above, and the little one attacked from below. Simultaneously they injected venom into him, and soon there was a dead fly to divide between them. The small spider, who had fought and worked valiantly, came up to claim his share, and his treacherous coadjutor seized him by the back of the neck and pitched him out of the web—which shows that alliances between the weak and the strong are as unsatisfactory to day as they were in Æsop's time.

ONE TO NINE.—The longest monosyllabic words in the English language are the following nine-letter words: Scratched, stretched, scrunched, scranched, screeched, squelched, staunched, schreight, splotched.

ANCIENT BAKERY.—The oldest bakery now in existence is that belonging to Master-baker Dietrich, in Frankfurt-on-Main, it being mentioned as early as the year 1421. It was, however, first used as a bakery in 1467. A room dating from 1603 is still in good preservation, and this, with a beautiful inlaid shrine, dating from 1614, are among the curiosities of the house. The shrine was discovered by the owner during the course of some repairs in 1763, and is a remarkable piece of work, said to have been done by Johann Caspar Arzt.

TEMPERING TOOLS.—The following is said to be the Swiss method of hardening cast steel for cutting tools. Mix in a suitable vessel four parts of pulverized resin and two parts of train oil. Stir well in this one part hot tallow. Into this mixture the article to be hardened is plunged at a low red heat and held there until thoroughly cooled. Without cleaning off, the piece is again put into the fire and suitably tempered in the ordinary way. An examination of steel thus hardened indicates that the hardening is deeper and more uniformly distributed than is commonly the case, and that the steel is less brittle. Articles thus hardened have excellent and durable cutting qualities.—*Stone.*

WATCHES.

EVERY one wants a watch, and naturally a good watch that keeps accurate time, presents a handsome appearance, and is inexpensive. If such a watch can be found of American manufacture, it is an additional appeal to our patriotism. Just such a watch as this ideal THE ANALYST PUBLISHING COMPANY is enabled to offer as a Premium to its readers. Having some large advertising contracts we have been enabled to procure the movements of the manufacture of the best known American watch factories, namely, the Waltham, Elgin, Hampden and Illinois Watch Companies. These movements are adapted for both ladies' and gentlemen's watches, and are warranted by the makers. These movements have seven jewels, patent lever movement, chronometer balance, patent safety pinion, sunk hard-enameled dial, straight line visible palette, stem winders, hand set; in fact, contain all the latest improvements and can be readily cleaned or repaired by any ordinary good watchmaker. They can be regulated to run as close as any movement.

It is needless to say that to case these movements in solid gold cases would make them too expensive, yet they are cased in what are known as gold filled or stiffened "Ladd" cases, and are warranted to be 14 karat gold, made from two sheets of 14 karat gold overlaying fine composition metal, with regular jointed caps, covers and bezels, and to wear at least five years. They are not plated, nor rolled gold, but actual 14 karat gold cases, thin of course, but stiffened and strengthened by being filled with this fine composition metal. They are finished in the same manner, engine turned and engraved as solid gold watches, and wear and look just the same. No one but an expert can tell them from a solid gold watch. These watches are made both open face and hunting case style, in gentlemen's or ladies' sizes. For gentlemen we recommend plain engine-turned cases; for ladies, a handsomely engraved case.

How to Obtain One of these Watches.

These watches are not to be purchased from us at any price. Send us a club of 25 subscribers to the AMERICAN ANALYST, and $25, the regular subscription price, and one of these watches (your choice of style and size) will be immediately forwarded, post-paid and registered, to your address. You need not wait until you have your 25 subscribers all together, but forward them as you get them and they will be credited to you, and when the number is complete the watch will be sent. A subscription for two or three years will be counted as two or three subscribers.

As these watches are retailed by jewelers at not less than $25, it will be seen that we are offering a real premium with the sole object of increasing our circulation, and that by taking advantage of our offer any one can obtain a good, reliable and handsome watch without cost. As the number of these watches at this price is limited, it is advisable to take steps at once to procure a bargain.

THE ANALYST PUBLISHING CO., 19 PARK PLACE, NEW YORK.

BICYCLES

GIVEN AWAY TO BOYS AND GIRLS!

AN OPPORTUNITY OPEN TO ALL.

The Analyst Publishing Company being desirous of largely increasing their subscription list, will furnish every one with a beautiful Safety Bicycle, ABSOLUTELY FREE, in return for a few hours' canvassing.

To every boy and girl who secures 75 subscribers for the American Analyst at $75, we will give a splendid

$40.00

NONPAREIL

SAFETY BICYCLE.

These bicycles are adapted in size to boys, but are strong enough to carry a man. A boy's bicycle should be a strong one. They are manufactured by the OVERMAN WHEEL CO., the makers of the celebrated VICTOR Bicycle, and have the full guarantee of the makers.

The following is a brief description of the NONPAREIL SAFETY; 26-inch wheels; ball bearing all around, including pedals; solid crescent rims; double tangent spokes; three-fourths inch tires; cranks, three throw, $4\frac{1}{4}$ to $5\frac{3}{4}$ inches; guards to both wheels; tool-bag, oiler and wrench. Finished in bright enamel, all exposed metal heavy nickel-plate on copper.

In selecting these machines as a premium, we have disregarded cheapness and selected a Bicycle which is serviceable, and the makers of which have an established reputation for building the best Bicycle that money, machinery and brains can produce. We are actually furnishing the Bicycles and Papers at less than cost, but hope by stimulating active and successful canvassing, and thus enlarging our subscription lists, to make an eventual profit. We positively guarantee these bicycles to be just as here represented. They will be shipped by express f. o. b. in New York.

Subscription orders must be made out plainly and legibly, and sent as fast as secured, addressed to

No. 57. **Rosedale Cottage, 3 Rooms.** With Bay Window, Frame. Cost, $1,000.

TABASCO PEPPER SAUCE,

OR LIQUID PEPPER.

Is simply the Pulp of the Ripe Pepper Extracted by Pressure.

The seed of this Pepper was obtained from Central America, and by careful cultivation in Louisiana for many years has been so improved in strength, flavor and aroma, as to have become a new variety of Red Pepper, superior to all others. The pulp is so handled as to retain all the flavor, strength, aroma and color of the ripe fruit, and to keep unimpaired in any climate. It excites the appetite, promotes digestion, and is pronounced by connoisseurs to be the finest condiment in the world. For medicinal purposes it recommends itself by its purity, strength and diffusible form.

Manufactured by E. McILHENNY'S SON,

NEW IBERIA, LA.

For Sale by all Wholesale Grocers.

INSTRUCTIONS TO SUBSCRIBERS.

The **Names of all Subscribers** are registered as soon as received, and paper is always promptly forwarded.

Postage.—The postage to all parts of the United States and Canada is paid by the publisher.

Remittances of small sums may be made with comparative safety in ordinary letters. Sums of one dollar or more must be sent by registered letter or P. O. money order, otherwise we cannot be responsible for same. Silver must not be sent in a letter.

Postage Stamps will be received for the fractional part of a dollar, and in any amount when it is impossible for patrons to procure bills, but you must send one or two-cent stamps only.

SUBSCRIPTIONS.—The AMERICAN ANALYST will be sent one year to any subscriber for ONE DOLLAR. New subscriptions can begin at any time.

We Stop the Paper at the expiration of the time paid for unless a renewal of subscription is received. Those whose subscriptions have expired must not expect to continue to receive the paper unless they send the money to pay for it.

Change of Address.—Subscribers wishing their addresses changed must invariably give their former as well as new address.

Missing Numbers.—It occasionally happens that numbers of our paper sent to subscribers are lost or stolen in the mails. In case you do not receive any number when due, write us a postal card and we will cheerfully forward a duplicate of the missing number.

Most Important of All.—In every letter that you write us, never fail to give your full address, plainly written—name, post-office, County and State.

Address all letters to

THE ANALYST PUBLISHING CO.,

GRAND PREMIUM OFFER!

A SET OF THE

WORKS OF CHARLES DICKENS,

In Twelve Large Volumes,

Which we Offer with a Year's Subscription to this Paper for a Trifle More than Our Regular Subscription Price.

CHARLES DICKENS.

Wishing to largely increase the circulation of this paper during the next six months, we have made arrangements with a New York publishing house whereby we are enabled to offer as a premium to our subscribers a **Set of the Works of Charles Dickens**, in **Twelve Large and Handsome Volumes**, with a year's subscription to this paper, for a trifle more than our regular subscription price. Our great offer to subscribers eclipses any ever heretofore made. Charles Dickens was the greatest novelist who ever lived. No author before or since his time has won the fame that he achieved, and his works are even more popular to-day than during his lifetime. They abound in wit, humor, pathos, masterly delineation of character, vivid descriptions of places and incidents, thrilling and skillfully wrought plots. Each book is intensely interesting. No home should be without a set of these great and remarkable works. Not to have read them is to be far behind the age in which we live. The set of Dickens' works which we offer as a premium to our subscribers is handsomely printed from entirely new plates, with new type. The twelve volumes contain the following world-famous works, each one of which is published *complete, unchanged, and absolutely unabridged:*

DAVID COPPERFIELD,
MARTIN CHUZZLEWIT,
NICHOLAS NICKELBY,
DOMBEY AND SON,
BLEAK HOUSE,
LITTLE DORRIT,
OUR MUTUAL FRIEND,
PICKWICK PAPERS,
BARNABY RUDGE AND CHRISTMAS STORIES,
OLIVER TWIST AND GREAT EXPECTATIONS,
THE OLD CURIOSITY SHOP AND THE UNCOMMERCIAL TRAVELER,
A TALE OF TWO CITIES, HARD TIMES AND THE MYSTERY OF EDWIN DROOD.

The above are without question the most famous novels that were ever written. For a quarter of a century they have been celebrated in every nook and corner of the civilized world. Yet there are thousands of homes in America not yet supplied with a set of Dickens, the usual high cost of the books preventing people in moderate circumstances from enjoying this luxury. But now, owing to the use of modern improved printing, folding and stitching machinery, the extremely low price of white paper, and the great competition in the book trade, we are enabled to offer to our subscribers and readers a set of Dickens' works at a price which all can afford to pay. Every home in the land may now be supplied with a set of the great author's works.

GLENN'S SULPHUR SOAP.

Glenn's Sulphur Soap is the **Original** and **Best** combination of its kind, and the one now generally in use. For sale by **All Druggists.**

BEWARE OF COUNTERFEITS.

Wholesale Depot,

C. N. CRITTENTON,
115 FULTON STREET,
NEW YORK.

Be progressive and keep abreast of the times. Avoid dyspepsia by using **Lard Compound** and **Cottolene,** a substitute for lard.

The highest medical authorities pronounce them healthful; and expert cooks commend them.

Our **Clairette** brand of cotton oil soap is the purest and best laundry soap in the market; as pleasant to the hands as genuine castile.

N. K. FAIRBANK & CO.,
CHICAGO AND ST. LOUIS.

OUR GREAT OFFER

TO SUBSCRIBERS

TO THE

AMERICAN ANALYST.

We will send the **ENTIRE SET OF DICKENS' WORKS,** *in* **TWELVE VOLUMES,** *as here described, all postage prepaid by ourselves, also* **THE AMERICAN ANALYST** *for* **ONE YEAR,** *upon receipt of* **$1.50,** *which is only* **50** *cents more than the regular subscription price of this paper.* Our readers, therefore, practically get a set of Dickens' works in twelve volumes for only **50** cents. This is the grandest premium ever offered. Up to this time a set of Dickens' works has usually been $10.00 or more. Tell all your friends that they can get a set of Dickens' works in twelve volumes, with a year's subscription to **THE AMERICAN ANALYST** for only **$1.50.** Subscribe now and get this great premium. If your subscription has not yet expired, it will make no difference, for it will be extended one year from date of expiration. We will also give a set of Dickens', as above, free and post-paid, to any one sending us a club of three yearly subscribers.

SUBTERRANEAN INVESTIGATIONS.

This is certainly an age of scientific progress. It would be a superfluous task to enter upon a trite recapitulation of the wonderful discoveries that give this generation its preeminence over all its predecessors, but an interesting enumeration might perhaps be made of the unfinished schemes now in progress or under serious advisement for wresting from nature still more of her hidden mysteries. Thus, while one set of philosophers are experimenting with the surrounding atmosphere, hoping to obtain a mastery over the moisture suspended in the clouds, or to gain control of the electrical currents supposed to be coursing through the ether, others are turning their minds and efforts downward toward the centre of the globe we inhabit. During the last two sessions of Congress there has been serious discussion of a Government appropriation for boring a hole in the earth several miles in depth. It has long been recognized that an inconceivable amount of value in the shape of metals and mineral substances is locked up out of reach beneath the crust of this planet. All the riches dug out of it represent merely the most superficial and ineffective scratching of the surface. Geologists are agreed that the interior of the earth is largely composed of metals. Whereas the surface matter of the planet weighs only about two and one-half times as much as water, it is known as a fact that towards the centre the average weight of things is eleven times that of water. This is due to the circumstance that while this sublunary orb was cooling and condensing the heavier particles sought the middle. Therefore it is probable that the great mass of the sphere is iron. But there are other metals more heavy than iron, and these would naturally form an accumulation immediately about the centre of the globe. So it is not unreasonable that certain members of Congress and other persons of keen judgment should consider the advisability of boring a hole in the earth for the purpose of extracting some of its metallic contents. For scientific purposes a pit has recently been sunk at Speling, in Germany, to the depth of a mile. Unfortunately, water has been struck, and no results which add very materially to human knowledge have thus far been obtained. Another well has been driven at Wheeling, W. Va., as far down as three quarters of a mile. It is dry, and the boring process is proceeding at the rate of about ten feet a day. Estimate is made that at twenty miles from the surface of the earth every known substance—metals, rocks and all—becomes fused and liquid. Once let the point be reached, and naturally whatever is below must spout up of its own accord, without expense of mining. Immediately the price of metals in the market would be reduced to little or nothing, and a new age would dawn upon civilization. It has been suggested that such an artificial conduit would be, to all intents and purposes, a volcano; but any dangers which it would otherwise threaten might be obviated easily by establishing the works on an open prairie.

A CONCESSION.

The AMERICAN ANALYST, replying to our article in which we took it to task for its aspersions upon the grocery trade, speaks of "Pure Food" Exhibitions as humbugs. Let us say to it, here and now, that the Boston grocers never called their Exposition a Pure Food affair, but a Food and Health Exposition. No one can exactly determine what pure food is, but it can determine what wholesome food is. Some of the best preparations are not pure—if pure they would have little or no merit. * * * * * * THE ANALYST, in trying to show that grocers use sophisticated goods, quotes as an editorial utterance of this paper a quotation from the Holyoke and Fall River daily papers, as explicitly stated when we published the same. The very item it publishes from the *Voice* it would denounce as an exaggeration. It knows that a good deal of this adulteration talk is humbug. At the same time it does exist. But we claim the grocer is not the only sinner.

The above is from the *New England Grocer* of recent date. It is gratifying to observe that our highly esteemed contemporary admits that the phrase "Pure Food" could not appropriately be applied to the money-making schemes which are becoming popular under the flimsy pretext of Food and Health Exhibitions. That is the case in Boston and New York alike. It is also gratifying to see our contemporary concede that the grocers sometimes handle sophisticated goods. We should judge, in fact, that the evil referred to prevails in his locality to a larger extent than it does in this metropolis. The Boston *Herald* of July 9 asserts that the Massachusetts State Board of Health, in a list of twenty of the most common articles of food in use in every family, finds that there is 32 per cent. of adulteration. This exhibit would be most alarming if the list included all that was used in the household economy for the supply of the table for adults and children. Fortunately, however, there are certain staple products, such as sugar, flour, and other cereal products, which are rarely adulterated, and therefore need little inspection. The report of the board, which has just been issued, shows an examination of 434 specimens, gathered at random, and subjected to analytical examination. Of these, 295 were found to be of good quality, while 139 were adulterated, varying from the legal standard. The most alarming exhibit reported from the examinations was in the matter of canned goods, where only one-seventh of all the specimens were found to be of such quality as to warrant the seal of approval.

POISONOUS DYES.

Concerning the much discussed question as to how far organic dyestuffs are detrimental to the human system, Dr. Theo. Weil asserts that, except gamboge, which has been declared to be poisonous by an imperial German law governing the subject, and certain berries used for dyeing wine, the natural dyestuffs are entirely innocuous; and, of the artificial organic dyestuffs, the law in question mentions only two as being poisonous, namely, coraline and picric acid. In regard to the general belief that most of the coal-tar colors are poisonous—or, as it is commonly termed, poisoning produced by wearing clothing dyed with aniline—Dr. Weil is of the opinion that most of these cases are based upon exaggerated statements or incorrect observations—because, if the tar colors were really as detrimental as represented, the cases of poisoning, in view of the almost universal employment of those dyes, both for coloring fabrics and food products, would be far greater, and, in especial, the workmen employed in manufacturing them would be subject to constant illness, which does not appear to be their experience.

The amount of so-called scientific information which is sheer nonsense that is being printed nowadays, would be ludicrous if it were not sometimes dangerous. People reading such items as the above coming apparently from good authority are lulled into a sense of false security from which they can be only aroused when they have by bitter experience learned that the information was erroneous. This article contains a great deal of truth, but the danger lies in much truth

that is hidden from the non-professional reader by the bold assertion for instance, that coal-tar colors are non-poisonous. While it is true that the coal-tar colors in themselves may be non-poisonous, yet when they are prepared with arsenic as the oxydizing material they are in the highest degree poisonous. Red, green and yellow coal-tar colors are generally thus made with arsenic and for that reason alone fuchsine, as sold commercially, is well known to be dangerous. Of course, fuchsine is made free from arsenic by repeated washing and recrystallizing, but this makes it too expensive for ordinary use, and consequently nearly all turkey reds so extensively used in carpets, hosiery, wall-paper, and even in coloring ice-cream, confectionery, and wine, has often produced dangerous results. The yellow color produced from coal-tar called naphthaline, made as a nitrous compound has been found equally poisonous. Stockings in the dyeing of which antimonial salts have been used as a mordaunt have caused ugly ulcerations. The argument that if these colors were really dangerous, their extensive use would make them more fatal is fallacious, because in their use great care is taken to employ but a small quantity, and where used in edibles much reliance is placed on the small quantity of the coloring necessary to produce the required color, and therefore the quantity of the poison taken into the stomach at any one time is ordinarily too infinitesimal to cause any direct noticeable effect. Another thing must be borne in mind, that is that while a small quantity of poison may not sensibly injure a strong healthy person, these things are all used for infants and invalids who are much more susceptible. In Massachusetts stringent laws have very properly been enacted to protect the public against these colors and it would be a great step in advance, if other States would follow the example. The AMERICAN ANALYST has from time to time given instances enough of such poisoning to warrant stringent repression.

ANTEDILUVIAN MONSTERS.

A WONDERFUL COLLECTION OF PREHISTORIC BONES.

There will shortly be started for Washington, writes Rene Bache, the most extraordinary procession of animals ever seen on the face of the earth, upon which the ghosts of Barnum and Forepaugh might gaze with as wide-eyed astonishment as ever the spectacle of their own United Shows excited in the innocent minds of rural adolescence. In this wonderful parade will be gigantic reptiles as big as good-sized houses, some of them 100 feet in length, flying dragons with a twenty-five foot spread of wings, huge birds with teeth, mammals two or three times as great in size as elephants, sharks as large as the hugest whales, other fishes clad in mighty plates of armor, and countless specimens more of equal strangeness and enormous dimensions, such as actually inhabited the world before man arrived in it. For nine years past the Government has been digging up and putting together the skeletons of these strange creatures, and now the vast collection, at the present stored in New Haven, Conn., is being got ready for shipment by rail to the National Museum. The whole of it would occupy fully one-half of that institution's building, and so only a portion is to be immediately forwarded, the rest to follow as soon as quarters have been established by Congress for its accommodation. The business of digging for these tremendous fossils is carried on pretty much like any other mining. In various parts of the West there are great deposits of them, into which the scientific enthusiasts eagerly delve for relics of epochs thousands of centuries old. One of their chosen hunting grounds is the region between the Rockies and the Wasatch Mountains. Ages ago the upheaval of these hills by geologic action cut off the portion of what had been sea between these ranges from the ocean, and the water thus shut away formed many big lakes. A typical one of this sort existed in Wyoming, and around it the mighty antediluvian mammals gathered in herds to crop the succulent and luxuriant vegetation of what was then a tropical climate in that region. They died natural deaths or became mired in the mud when they went to drink, and the sediment slowly deposited in the water covered up their bones and preserved them from decay. This sediment reached a mile in thickness, holding between its layers these ancient skeletons, distributed like currants through a cake. At length the water, draining off, left the land dry, and, in the case of the Wyoming lake referred to, subsequent floods washed away much of the sediment previously deposited, leaving what are now called "bad lands"—picturesque with cliffs, peaks, and columns carved out in fantastic shapes and of variegated coloring. Through such a region as this the scientific explorer travels with his eyes as wide open for fossils as the gold hunter keeps his for the shining metal. If from the face of some rocky cliff he chances to see a bone project, exposed by the action of water that has cut away the hillside, he sets a party of men to quarrying with drill, blast, and pickaxe until whatever is there in the way of remains has been taken out. Possibly some great deposit of prehistoric monsters may be struck in this way, in which case the find is kept as secret as possible, being regarded by the discoverer as his private mine. If he gave it away, rival paleontologists would rush to the spot and dig out all the animals for their own study and glory. Prof. O. C. Marsh, who directed the gathering of the Government collection referred to, has such mines of his own all over the West, from which he can draw to order the most astonishing variety of gigantic creatures. Usually these amazing fossils are found embedded in solid rock. After they have been roughly quarried out, the sandstone or other matrix enclosing them is carefully chiselled away from the bones. The latter are given a coat of glue to keep out the decomposing air, and any that are broken or splintered are bound up with twine, after which they are packed for shipment. When one of these beasts of antiquity died, its carcase being covered up with sediment that afterwards became stone, the skeleton was apt to be preserved entire, and with its parts in position, all ready for mounting in a museum. There was a new reptile found in Wyoming the other day, in such a complete state, which has been named the brontosaur. It was 60 feet long, stood 15 feet high when alive, and weighed 20 tons. Cast in the rock from which it was taken was a perfect mould of one of its eyeballs, with which it looked upon the world three millions of years ago. It had a very small head, a long and flexible neck, a short body and a huge tail. In the same neighborhood has also been discovered recently another reptilian monster called the triceratops, which had an enormous bony frill around the back of its neck. This surprising development, measuring six feet across, was intended for the attachment of great muscles that were necessary holding up the huge head. The animal, though tremendously massive, was only thirty feet long; but it was covered with plates of armor and had a sharp and horny beak, not to mention a horn on its nose and another on its forehead, the latter two-and-a-half feet in length. In Colorado have been found great deposits of the bones of the titanosaur, the biggest land animals that ever existed. They grew to be sixty-five feet long, and forty feet high when erect upon their hind legs. Instead of browsing, as did the brontosaur and triceratops, upon the luxuriant aquatic vegetation around the lake borders, they feed upon the foliage of trees on the mountain sides. Likewise did the iguanodon, several times as heavy as an elephant, which had a nipping beak like a turtle's and also walked erect, using its huge tail for a support, and towering to the height of forty or fifty feet. In the Mesozic epoch, or "age of reptiles," when the creatures described lived, these and other similar herbiverous animals were the biggest of the beasts. One of them, the attlantosau, was one hundred feet long, its thigh bones, many of which have been found, measuring eight feet in length and twenty-five inches through. They had various methods of pursuing existence. Some went on all fours, and had backbones that were mere shells filled with warm air from the lungs, which served them as floats while they walked in the sea shallows in water deep enough to cover their backs, extending their long necks to crop the vegetation along shore. Of this sort was the camera-saurus, eighty feet in length. Others had enormously long hind legs, on which they were able to wade out far into the ocean after seaweeds, and were provided with not fewer than two thousand teeth for grinding their food. Such was the mighty kangaroo-like hadrosaurus. Yet other species dwelt on land, like the triceratops, and these were usually provided with armor and horns for defence against their enemies. It would seem as if such monsters as are above described need have feared no living foes, but, in fact, they were common prey to great numbers of carnivorous reptiles, smaller in size but of tremendous activity and fierceness, which fed upon these unwieldly vegetable-eating giants. Most terrific of all, perhaps, was the incredibly ferocious lælaps, which was forty feet long, stood twenty-five feet high on its hind legs, and was built like a kangaroo. It was the most astonishing jumper that ever existed, with teeth for cutting and sharp claws on the front feet that were evidently designed for tearing out the eyes of victims or adversaries. Hardly less formidable and equally large was the stegosaur, which was sheathed in armor plates from two to three feet in width, and employed as a weapon of offence its powerful tail, armed near the end on both sides with sharp spikes two feet long. This animal walked erect, also, and one of its peculiarities was a great enlargement of the spinal cord at the lower end of the back. In fact this expansion of brain-material, intended to provide for the wagging of the mighty spiked tail, was ten times as big as the brain in the skull itself. Equally large and dangerous were the megalosaur and the dinosaur—their jaws armed with hugh sabre-like teeth—which went about on their hind legs looking for something to devour. Against such fearful foes what chance had the peaceful cetiosaurus and elasmosaurus, dwelling in marshes and shallows, with the bulk of six or eight elephants? Nevertheless, some of the herbivorous land reptiles referred to, like the gigantic horned and armored agathaumas, could make a good fight with the carnivores, and were so well able to defend themselves that they lived and multiplied in the same regions with the latter. But most of these vegetable feeders had no other means of defence than kicking, which they could do with some effectiveness, with their hinder limbs fifteen feet or so in length. Specimens of all these are included in the collection that is to be brought for permanent exhibition. Of course they represent but a few of the countless species of giant beasts that roamed over the earth in droves during this vanished epoch. That was the age when reptiles ran creation. They walked upon land, swam the seas, flew through the air, climbed trees, and did everything that mammals do nowadays. There were bird reptiles and reptilian birds. Some had wings for flying with a spread of twenty-five feet—veritable dragons, in fact. Others, forty feet in length, had paddles for swimming, like a whale's. These latter lived in the seas, though occasionally they came on shore. One species dived to great depths in the ocean, and was most rapacious and predatory. It had enormous eyes to see with in deep water, its head resembling an alligator's. Another kind, with a very long neck, inhabited the shoals and preyed upon the fishes of the shallows. The first serpents, too, belonged in the sea and grew to be forty feet long. They had no poison, but were constrictors like the boa. There were many kinds of crocodiles, fifty feet from snout to tail, whereas the biggest ones now are not more than fifteen feet. During the same period lived the birds with

teeth, which were only discovered a few years ago. Biggest of these were the hesperornis, which stood six feet high and had only rudimentary wings. It did not fly, therefore, but was simply a swimmer and diver, subsisting on fish. The ichthyornis was somewhat similar in appearance and habits, but not much larger than a pigeon. It is supposed that these strange waterfowl were wiped out by the giant swimming lizards, eighty feet long and clad in bony armor plates, which resembled the modern conception of the sea serpent. The turtles should not be forgotten, which attained a length of twenty feet and measured seven feet in height. It is not only the age of reptiles, however, that is represented by the unparalleled collection described. Before that came the epoch of the fishes, when they ran the world and had all creation pretty much to themselves. Of this era likewise the Government has gathered together a vast quantity of fossil relics. The face of the earth did not look then at all as it appears now. Most of what are now called continents had not been upheaved above the ocean. Nearly everywhere was sea, with comparatively small land masses elevated out it. The atmosphere was hot, moist, and loaded with carbonic acid so as to be unbreathable. In the ocean swam enormous armored fish, such as the dinichthys, which was fifteen feet long, and had such tremendous jaws and teeth that it could have bitten a man in two as easily as you would a radish. Later on came sharks of the fiercest type, which must have been as much as seventy feet in length at least. The biggest tooth of a man-eater of to-day is about an inch long, while the teeth of the ancient sharks, which are found in enormous numbers, measure more than six inches. This was the golden age of the scaly tribe. The giant reptiles that appeared on the scene in the subsequent epoch were remarkable for the smallness of their brain cavities. In some of them the brain was so small that it could have been passed without injury through all the vertebræ of the spinal column down as far as the beginning of the tail. All of them were wiped out of existence by the great cataclysm which upheaved the Rocky Mountains, the Alps, and the Himalayas, and brought to a close the Mesozoic epoch. Then came the Age of Mammals, at the end of which we are now, man being the last arrival on the scene. The age of monsters has pretty nearly passed away; only a few remaining, like the elephant and the whale. Small animals with plenty of sense will always survive stupid giants in the long run, because they require less food and know better how to avoid danger. Observe in illustration how the doom of extinction has fallen upon the gigantic mammals which roamed over the earth by myriads only so short a time ago, comparatively speaking, as the beginning of the present era, called Cenozoic. There was the dinoceras, which lived in herds about the lakes, as the deposits show—big as an elephant, but in appearance somewhere between the rhinoceros and the hippopotamus, with three pairs of horns on its head, and huge sabre-like tusks that fitted into sheaths in the lower jaw. More imposing yet was the tinoceras, somewhat similar of aspect, and sixteen feet long. Not less impressive was the megatherium or giant sloth, as large as two elephants, which attained a measurement of eighteen feet, and procured the leaves on which it fed by seating itself upon its mighty haunches and uprooting great trees. Of the dinotherium no complete skeleton has been discovered, but it was doubtless the biggest land mammal that ever lived. A full-grown skull of this earliest of proboscidians, which had long tusks as well as a trunk, measures five feet irom the point of the lower teeth to the top of the head. The brontops, of elephantine size, had a head like an rhinoceras with big horns. Quite as remarkable was the sivatherium—a beast like an antelope, but big as an elephant—with two conical horns on the front of its head, and two immense spreading ones behind. Among birds were waders ten feet in height, such as the dinornis and gastornis. Contemporary with them were the mammoth and the mastodon, the woolly rhinoceros, armadillos nine feet in length, and the sabre-toothed tiger, larger than the greatest lion of to-day. All that is left of these wonders of animal life is found in deposits such as those of the Western lake beds. For years the Government has been engaged in excavating their bones, which are now to make part of what is destined to be the greatest zoological show on earth.

LEUCOCYTES.

THE WHITE CORPUSCLES THE WARDERS OF THE BLOOD.

Our body is composed approximately of thirty billion cells, the primary units of life. Not only are they the material particles out of which our organism is built, but they form the foundation for the functions of all our organs. What we commonly call life is nothing else than the sum of the functions of all the cells. The complicated mechanism of the human body exists and is kept in working order only by the intimate co-operation of a number of separate living beings far transcending our powers of conception. Yet each infinitesimal being lives in and for its individual self and not for the whole mechanism; it breathes, takes sustenance to itself, and gets rid of the used-up material. That such a cell is capable of life as a separate individual can be seen in the amœbas, those smallest of animalcules, which consist of nothing more than a mass of protoplasm enclosed in an extremely thin membrane, exactly like the cells of the human organism. An exceedingly interesting variety of these cells is what are called the leucocytes, the "chimney-sweeps of the blood," as a famous living physiologist has characterized them, which were known in the last century, but whose functions we do not entirely understand to this day. These leucocytes, which are of microscopic size, are present in the blood in the form of "white blood corpuscles," in the proportion of one to every three or four hundred red corpuscles. The proportion is entirely different in consumptives or persons suffering from leucocythemia, who harbor in their blood a great excess of the white corpuscles. This, and not, as many suppose, deficiency of blood, is the true cause of consumption. Leucocytes are found not only in the blood vessels, but also in the spleen, the liver, and many other organs. The construction of the white blood corpuscles is very simple. They consist of a soft, semi-fluid mass called protoplasm, which contains one or two nuclei, and the whole is surrounded by a fine membrane or cell wall They are globular in shape and are larger than the red corpuscles, which have neither nucleus nor membrane. Their movements also are different from those of the red corpuscles, which shoot through the middle of the stream of blood, while the white roll along the wall of the blood-vessel. Sometimes three or four are seen close together, and again they are found widely separated. Like the independent animalcules that have been mentioned, the amœbas, the leucocytes are able to change their shape at any time by forming pseudopods. A part of the mass contracts and throws out an irregular process, which in turn buds into a new one or several. These pseudopods serve the amœbas as a means of taking food and of locomotion, and they perform the same offices for the leucocytes. If these come to a narrow blood-vessel, they elongate themselves and thus slip through, to resume afterward their original form. Besides their ability to change their shape, they possess another very remarkable property that shows what an important part they perform in the animal economy and has justly earned for them the name of "nomad cells." This is the power of leaving the blood-vessels by breaking through their walls. When a leucocyte wants to migrate—the operation takes place in the finest and smallest of the blood-vessels, the capillaries as they are called—it first throws out a kind of pseudopod, a filament of exceeding fineness, which bores its way through the tissue of the wall. When it reaches the outer side, minute granular particles of protoplasm are sent along the thin appendage, and these collect in a small bunch on the outside ol the membrane. This process goes on until the entire leucocyte has passed over to the outer surface of the membrane, whence it pursues its journey into the interior, penetrating the tissues. This faculty, interesting and unique as it is, would not give the leucocytes such physiological importance if it was not supplemented by another equally interesting peculiar property. This consists in their ability to render innocuous any alien substance that has got into the blood-vessels in any way. Whenever a leucocyte comes in contact with such a foreign body it seizes and holds it fast by throwing about it a pseudopod, and then gradually envelops and absorbs it. This is a fact that can be proved by experiment. If we introduce a foreign substance into the blood, for example, fine powdered indigo, we will find that in a comparatively short time, perhaps twenty-four hours, it will disappear entirely from the plasma. The leucocytes have taken it up, loaded themselves with it, as we can see from their altered color, and thus removed it from the blood. They thus cleanse the blood passages, sweep out every kind of refuse, and keep the road always clear for the ceaselessly pulsing vital stream. They will allow no poison as a destroyer of life to gain the mastery in the blood fluid. They will fight with it to the death, and ofttimes their valiant struggle is crowned with splendid success—a human life saved. If the forces of the enemy are stronger than they, still they will never give up the fight till the last of their band has fallen.

GUNNY BRICKS.—Old bagging is being worked up into bricks for artistic decorations.

DEODORIZER.—A few pounds of copperas dissolved in a bucket of water and sprinkled in cesspools or any place emitting foul smells, will purify and sweeten them.

COLD GAME.—Frozen game partakes and absorbs whatever impurities the ice may contain, and everybody knows that the best quality of ice is never used for packing.

NEW MACHINE.—A planing machine for making tooth gearing, which forms the tooth direct out of the solid by a specially shaped cutter, has been brought out by M. Herman Michaelis, of Chemnitz, Saxony, Germany.

DANGEROUS PETS.—A French scientist declares that the domestic pets of the world carry at least thirty per cent. of the common contagious diseases from house to house.

READY FOR USE.—The only proper way to keep a gun barrel in good order is to wash it out with boiling hot water, dry with linen swabs, and oil with vaseline or cylinder oil every time that it is used. It should never be laid aside unattended to for a day or two after firing.

WOMEN PROGRESSING.—The Attorney General of Maine gives an opinion that women may legally hold the position of members on local boards of health in that State. Appointments of women on these boards have been made this spring, and the secretary of one board is a woman.

GOOD RULE.—Rosenberg, Senior—"Simon, my boy, now that you are going into business for yourself, let me gif you von good rule to follow." Rosenberg, Junior—"Vell, fader?" Senior—"It's dis; if your customers don't see vat dey vant, make dem vant what they see."—*Yankee Blade.*

BACTERIOLOGY.—In science a writer says that while as yet we have discovered no way of avoiding contagion which comes to us in the air, we are beginning to find out the important fact that the air does not become contaminated with bacteria unless they are allowed to dry. Recent investigations, he adds, have shown a smaller number of bacteria in the air of a well-kept sewer than in that of a poorly-ventilated school-room.

MONKEY TALK.

UTILIZING THE PHONOGRAPH TO FORMULATE A SIMIAN LANGUAGE.

Professor F. L. Garner writes as follows to the *New Review* (London) for June: I have long believed that each sound uttered by an animal had a meaning which any other animal of the same kind could interpret at once. I regarded the task of learning the monkey tongue as very much the same as learning that of a strange race of mankind—more difficult in the degree of its inferiority, but less in volume. Year by year, as new ideas were revealed to me, I began to realize how great a task was mine. One difficulty was to utter the sounds I heard; another was to recall them; and yet another was to translate them. At last came a revelation. I went to Washington, and proposed to Dr. Frank Baker, Director of the National Zoölogical Garden, the novel experiment of acting as interpreter between two monkeys. The plan was quite simple. We placed in separate rooms two monkeys that had been caged together. A phonograph recorded a few sounds uttered by the female. When the male heard these sounds repeated, his surprise and perplexity were evident. He traced the sounds to the horn from which they came; he thrust his hand into the horn, withdrew it, and peeped into the horn again and again. Having satisfied myself that he recognized the sounds as those of his mate, I proceeded to record some of his sounds, but my success was not fully up to my hopes; yet I secured from him enough to win the attention of his mate, and elicit from her some signs of recognition. And thus, for the first time in the history of philology, the Simian tongue was reduced to record. I also secured phonographic records in the Chicago Zoological Garden, and in the Cincinnati Garden. I studied these, repeating them over and over, until I became quite familiar with the sounds, and improved my utterance of them. Some weeks later I returned to Cincinnati and Chicago, and tried my skill as a linguist with a success far beyond my wildest hopes. I stood by a cage containing a capuchin monkey. I uttered the word, or sound, which I had translated "milk." On repeating it three or four times he answered me very distinctly with the same word, and then turned to a small pan kept in the cage for him to drink from. I repeated the word again, and he placed the pan near the front of the cage and uttered the word. I gave him some milk, which he drank with great zest; then he held up the pan, and repeated the sound some three or four times. I was quite sure he used the same sound each time he wanted milk. I now held a banana in front of the cage, and he at once gave the word which I had translated "to eat." Repeated tests proved to me that he used the same word for apple, carrot, bread, and banana, hence I concluded that it meant "food," or "hunger," as also "to eat." From other experiments I was convinced that the word I had translated "milk" must also mean "water," and also "drink," and probably "thirst." I have never seen a capuchin monkey that did not use these two words. The sounds are very soft and quite flute-like; very difficult to imitate, and impossible to write. They are purely vocal, except faint traces of "h" or "wh" as in the word "who;" a very feeble "w;" and here and there a slight gutteral "ch." To imitate the word which I interpret "food," fix the mouth as if to whistle; draw the tongue far back and try to utter the "who" by blowing. The phonics appear to me to be "wh-u-w," with the consonant elements so faint as to be almost imaginary. In music the tone is F sharp, and this seems to be the vocal pitch of the species, though they have a wide range of voice. The sound I have translated "drink" or thirst is nearly uttered by relaxing and parting the lips, and placing the tongue as it is found in ending the German word "ich," and then trying to utter "ch-e-u-w," making the "ch" like "k," blending the "e" and "u" like slurred tones in music, and suppressing the "w." The consonant elements can barely be detected, and the tone is about an octave higher than that used for "food." My work has been confined chiefly to the capuchin monkey, because he seems to have one of the best defined languages of any of his genus. I have recorded one sound made by the sooty monkey; three by a mandril; five by a white-faced sapajou; and a few of less value. But from the best proofs I have found, I have arrived, as I believe, at some strange facts: 1. The Simian tongue has about eight or nine sounds, which may be changed by modulation into three or four times that number. 2 They seem to be half-way between a whistle and a pure vocal sound, and have a range of four octaves, and, so far as I have tried, they all chord with F sharp. 3. The sound used most is very much like "u"—"oo," in "shoot." The next one something like "e" in "be." So far I find no a, i, or o. 4. Faint traces of consonant sounds can be found in words of low pitch, but they are few and quite feeble. 5. The present state of their speech has been reached by development from a lower form. 6. Each race or kind has its own peculiar tongue, slightly shaded into dialects, and the radical or cardinal sounds do not have the same meanings in all tongues. 7. The words are monsyllabic, ambiguous, and collective, having no negative terms except resentment. 8. The phonic character of their speech is very much the same as that of children in their early efforts to talk, except as regards the pitch. 9. Their language seems to obey the same laws of change and growth as human speech. 10. When caged together one monkey will learn to understand the language of another kind, but does not try to speak it. His replies are in his own vernacular. 11. They use their lips in talking in very much the same way that men do. 12. I think their speech, compared to their physical, mental, and social state, is in about the some relative condition as that of man by the same standard. 13. The more fixed and pronounced the social and gregarious instincts are in any species, the higher the type of its speech. 14. Simians reason from cause to effect, and their reasoning differs from that of man in degree, but not in kind. To reason, they must think, and if it be true that man cannot think without words, it must be so of the monkey; hence, they must formulate those thoughts into words. 15. Words are the audible, and signs the visible, expression of thought, and any voluntary sound made by the vocal organs with a constant meaning is a word. 16. The state of their language seems to correspond with their power to think, and to express their thoughts. I have here given only a few of many trials which I have made to solve the problem of the simian tongue, and while I have gone only a step, I believe that I have found a clue to the great secret of speech, and pointed out the way that leads to its solution.

COMMUNICATING WITH MARS.

A WOMAN'S BEQUEST THAT SUGGESTS THE OLD "MOON HOAX" OF LOCKE.

A Paris cablegram says a French nun has bequeathed 100,000 francs to the Academy of Sciences, to be given as a prize to any one who shall discover any means of communicating with another world, planet, or star. The planet Mars was suggested in the will as the most convenient heavenly body on which to make the experiment. "This proposition may seem ridiculous, but it is not any more so than the idea of James Lick, the founder of the Lick Observatory," said a man well versed in starry lore to a *Chicago Tribune* writer. "The Lick bequest to build the great telescope was intended to establish the fact whether or not the moon is inhabited. Now let us consider the difficulties in the way of this project. The distance of the earth from the moon may be stated in round numbers as 240,000 miles. It is a fact recognized in military science that a man can be fairly distinguished by the eye at a mile's distance. In making calculations regarding vision it is the general rule to estimate that to be seen a mile away an object must be half a yard wide. The best telescope has a magnifying power of 2,000 diameters. Half the distance to the moon is 120,000 miles. Divide this by 2,000, the magnifying power of the glass, and you get sixty yards as the minimum size of an object in the moon discernible by the aid of the telescope from the earth. So an object must be 180 feet wide or thick to be more than an appreciable dot. I have made the most liberal allowances in this computation. The atmospheric conditions must be perfect, and 2,000 is an unusually high power to be used by an astronomer. If an object must be 180 feet thick to be seen from the earth on the moon, it would be best to make it 200 feet. To give the inhabitants of the moon an idea that there are intelligent beings on earth, it would be necessary to place, say, three objects in view of the moon's people. Let them remain for a time arranged at the angles of a triangle, then they might be changed so as to be in a straight line. The man in the moon, seeing these phenomena, might conclude that there were intelligent beings on earth, and arrange for some corresponding signal to the inhabitants of earth. But while this seems possible, it shows how preposterous would be the attempt to determine with the most powerful telescope now in use whether the moon is inhabited. Now, as to the proposed communication with Mars. At the time when Mars and the earth are nearest to each other—are in perihelion—the distance is in round numbers 35,000,000 miles. Take half this distance, and you have 17,500,000 as the number of yards that represents the size of on object in Mars that could be seen that distance with the naked eye. Divide this by 2.000, the power of the biggest telescope, and you have 8,750 the size of the smallest object plainly discernible at such a distance with the telescope. This is equal to about five miles. An object in the planet Mars could be perceived as a little larger than a dot with the aid of the largest refractor and under the most favorable, in fact absolutely perfect atmospheric and other conditions, if it was five miles in diameter. This is when the planet is nearest to us. On the other hand, at that time nothing on the earth could be discerned from Mars, because the earth would be in a straight line between the two and in the blaze of the sun's light. An inhabitant of that planet would have to wait until the earth was in some other part of its orbit, and the distance between the earth and Mars would then be many times as great as in perihelion. So it would be necessary to construct an object, to be discernible on the earth from Mars, say twenty miles in diameter. It might be circular in form. Other structures not inferior in size would have to be erected at distances of not less than twenty miles from each other. Then, after these had remained for a time, their relative positions might be changed. These bodies, moreover, to be clearly distinguished from the surface of Mars, must be intensely luminous. A solid ball of electric light twenty miles in diameter would suffice. Considering the size of the structures required, their distance from each other, and the necessity of changing their places to indicate to a man in Mars that these luminous structures were the result of intelligent action and not natural phenomena, the sum bequeathed by the French nun may be seen to be greatly inadequate. The Academy of Sciences at Paris may for this reason refuse to accept the bequest. If the sum were offered for a prize essay on some plan for accomplishing communication with a sister sphere, it would be more reasonable. In all the above computations it must not be forgotten that all the conditions must be favorable, the atmosphere as well as the relative positions of the earth and Mars. Such conditions happen only once in a great while."

CHINESE SCHOLARS.

WHAT CONSTITUTES THE EDUCATION OF THE CHINESE "LITERATI."

A Chinese Mandarin, General Tcheng-Ki-Tong, gives the following interesting account of the Chinese higher education, in a communication to the *Asiatic Quarterly Review* for June: It is by no means uncommon to hear our Mandarin class, or "literati," spoken of as an all-powerful caste, in full possession of the country, and governing, according to its own good pleasure, other castes that yield a passive obedience to it, without any intelligence, and, above all without any influence. Nothing can be more unjunst to our "literati" than to describe them thus, for they are far from constituting a class separated from the rest of the nation. The "literati," in fact, are not recruited specially from among any certain number of families, for which are reserved the special appointments of administration and government. Favor has nothing whatever to do with it. The selection, on the contrary, is a most severe one, taking in the entire Chinese territory, and drawing out from the whole mass of the Chinese people the most capable individuals, to form of them the members of the corps of instructors and of the functionaries of the State. It is the examinations, open to all, which establish this selection. Neither birth nor fortune confer the claim to aspire to the title of a "literate." Nothing but the capacity of the individual can cause him to be admitted. There is no such thing, therefore, as "class" in this "personnel," which is constantly drawn from the inexhaustible reserve of our hundreds of millions of human beings, and which renews itself every year by new comers, recruited without distinction from all the social strata of the country. This popular origin has, moreover, in our eyes an enormous advantage. By the infusion constantly of fresh blood, our administration is always being rejuvenated, remains by that alone in permanent contract with the people, and can neither ignore nor forget the wants and asperations of the governed. With us, the son of a shopkeeper, of a mechanic, or of a laboring man can become a "literate" on the same conditions as the son of a "literate." The young man whose father modestly cultivates his patch of rice in some distant province, comes to Pekin in order to pass his last examinations. If he succeeds, he becomes at once, by this fact alone, one of the first of the class of "literates," and henceforth the highest appointments in the State await him. No "literate" will ever look upon, nor will he try to look upon, shopkeepers, artisans, or field laborers as belonging to a class less honorable than his own. Such an order of ideas would be perfectly strange to us, and I congratulate my country upon the fact. Instruction is not compulsory in China; nevertheless it is very rare to meet with an illiterate person. Our elementary instruction is, in fact, much more extensive than in Europe, the result of the greater difficulties attached to the learning of our writing, and to the multiplicity of our ideographic characters, acquaintance with which makes necessary long and careful application. As soon as a child is old enough to receive instruction, it is sent to some school, kept in a modest room, by a "literate" who, having acquired a very complete education, has not yet been successful in passing the examinations. Here the little boy learns to read, to trace his letters, to understand and to retain sundry precepts taken from our classics. By and by the pupil attacks literature, familiarizes himself with poetry, and anon, with history. Simultaneously he begins to learn drawing and painting in water-colors. He has to store his memory with a considerable number of literary extracts, and so to acquire gradually the style of our great writers. All this work has taken some years to get through, and the student prepares for his first examination, which corresponds to your bachelor's degree. Those who pass this, prepare for the second examination, and then for the third or doctor's degree. Successive eliminations reduce the candidates for the last degree to a very small number. At this examination, which is held every third year in the capital, out of ten thousand candidates, not more than two hundred succeed in passing. The studies of those examined have included, besides history and general literature, our practical philosophy, which is, in one word, the theory of the art of governing. Until very lately the sciences have found but little room among these studies; but during the last thirty years we have made the necessary effort in this direction, so that our special schools, combined with the missions of students sent abroad, suffice to bring us up to the level of our requirements. Our ancient national programme perfectly fulfills the the object for which we intended it. In effect, this programme develops, in the highest degree, public and private morality. It inculcates upon us, with the worship of the family and respect for our parents, the love of our neighbor and the desire to be happy through the happiness of all. We need not be moved by the reproach, which is sometimes made, of living in the past. If our "past" had been retrograde, I could understand the reproach. On the contrary, however, this remote past has bequeathed to us a doctrine of incessant progress, admirably suited to our natural genius. It has taught us that the family should always keep the happiness of all its members in view, that each individual should interest himself in the lot of all his fellow human beings—in a word, that the supreme object of government is the happiness of the people.

DOMESTIC DIETETICS.

SPECIALLY PREPARED, FROM PRACTICAL TESTS, FOR THE LADY READERS OF THE "AMERICAN ANALYST."

SEASONABLE FOOD.

July.

MEAT.—Beef, lamb, mutton, ham, kidneys, liver, sausage, veal.

GAME AND POULTRY.—Pigeon, chicken, duck.

FISH.—Anchovy, bass, bluefish, blackfish, cod, eels, clams, flounder, haddock, halibut, herring, lobsters, mackerel, mussels, perch, porgie, prawn, salmon, shad, turtle, trout, sturgeon, whiting, weak-fish.

VEGETABLES. — Beans, cucumbers, carrots, cauliflower, egg-plant, lettuce, onions, parsley, parsnips, potatoes, shallots, spinach, turnips, radish, rhubarb, corn, beets.

FRUITS.—Cherries, strawberries, raspberries, huckleberries, melons, gooseberries, blackberries, peaches, pears, tamarinds, bananas, pineapples.

PRACTICAL RECIPES.

RICE SOUP.—Wash four heaping tablespoonfuls of rice thoroughly and rub it dry; put it in a saucepan, pour a pint of cold water on it and let it heat very gradually, then add a pint of boiling water, and when it has cooked up pretty well add another pint of boiling water, using three pints of water in all. Beat the yolks of two eggs with four tablespoonfuls rich cream, Put a teaspoonful of butter into the soup and seasonings of salt and pepper; add the cream and eggs the last thing, let it cook for a minute, stirring all the time and serve at once.

GRIDDLE CAKES.—Make a batter of two cups dry biscuits crumbed fine, two cups milk, three eggs beaten separately, one cup flour, two tablespoonfuls of melted lard, salt. Mix perfectly smooth; put in the egg whites the last thing.

CREAM MAYONNAISE.—Put into a deep dish half a teaspoon of salt, a little white pepper, a little sugar and the yolks of three eggs. Beat them until very light, then beat in gradually, a few drops at a time, a cup of olive oil, thinned out a little with vinegar. Whip a cup of cream very stiff and just before sending to the table, beat it lightly into the dressing. If liked, a few drops of onion juice may be added before the cream is put in, but if only a very delicate flavor of onion is desired simply rub the dish in which you make the dressing with a cut onion.

PANNED OYSTERS.—Put twenty-five oysters with their juice into a saucepan over the fire, add two tablespoonfuls of butter, a little salt and cayenne pepper; sift in two large spoonfuls cracker crumbs and stir for a moment; let them boil up, pour into a tureen and serve.

LITTLE CINNAMON CAKES.—Beat together one half pound butter and one half pound sugar, add six eggs, eight cups sifted flour in which three teaspoonfuls of baking powder are mixed, a little salt and a teaspoonful of cinnamon. Roll very thin, cut out, sprinkle with sugar and cinnamon and bake. If the dough seems too stiff add a little milk.

DEVILED OYSTERS ON TOAST.—Mix together a heaping saltspoonful of mustard flour, half a saltspoon each of white pepper and salt, and the yolk of one egg. Dip six oysters in the paste, then in fine crumbs and broil over a moderate fire. When done, arrange on toast and squeeze over them the juice of half a lemon.

RATAFIA CAKES.—Pound together six ounces of sweet and two ounces of bitter almonds, blanched and dried, add as you pound them the whites of four or five eggs; when they are a smooth paste mix thoroughly with them a pound of powdered sugar. Lay sheets of white paper on baking tins and pour little drops of the mixture, the size of a nickle, on them half an inch apart. Sift fine sugar over them and bake in a moderate oven. Do not remove the cakes from the paper until they are cold.

THOUGHT AND LANGUAGE.

SOME SPECULATIONS ON THE EVOLUTION OF SPEECH.

Intuitional thinking is independent of language. To think is to construct an ideal whole according to a more or less definite plan. Thought appears to be independent of language and other expressive signs, only when the relations constituent of this ideal whole are capable of being presented in the focus of consciousness as immediate objects of vigorous and sustained attention. Now the effect of a vigorous and sustained attention is to make its immediate object distinct with the distinctness of a definite image, such as might be presented in actual sense perception. Hence it follows that thought, apart from words, can construct only such ideal wholes as are capable of being intuited. Independently of language the relations between the successive objects of attention which compose a train of thought must be, in the main, concrete and definite relations in space and time. Thinking of this kind we may, following the example of Steinthal, call intuitional thinking. Intuitional thinking may require strenuous and persistent intellectual exertion and high intellectual power. In playing chess, in manipulating algebraic symbols, in constructing a piece of machinery, words for the most part are not required. Aphasic patients, who have almost entirely lost command of language, may yet retain intact their skill at chess or cards. Since it is possible to think without the help of language, it is, therefore, possible to generalize without the help of language, for all thinking involves generalization. But though apart from language we can generalize with reference to the objects of our thought, yet these objects are not themselves general. Apperception, attention, and proportional production construct an ideal whole, according to a plan which is general, but the resulting ideal structure has the particularity of a percept. It is an intuitional whole, not a conceptional whole. This is and must be so, because the universal as such can never become an immediate object of attention. I propose to call the signs of lan-

guage, and all signs which fulfil a similar function, expressive signs. Under this head are included the natural signs of gesture language, the conventional signs of the manual language taught to deaf mutes, and all kinds of written language, as well as articulate speech. Expressive signs must be carefully distinguished (1) from suggestive signs, (2) from substitute signs. A suggestive sign merely calls up a certain idea which may then be attended to independently of it. It has fulfilled its purpose, and becomes of no further avail so soon as it has suggested its meaning. It is a mnemonic help. A substitute sign, on the contrary, is a counter which takes the place of its meaning; so long as it fulfils its representative function it renders useless all reference to that which it represents. The counters are manipulated according to certain rules of operation until a certain result is reached which is then interpreted. Algebraical and arithmetical symbols are to a great extent used as mere substitute signs. The same is true of the symbols used in formal logic. By means of expressive signs, mental systems which could otherwise only serve to apperceive objects of attention, become themselves transformed into objects of attention, apperceived by more comprehensive systems. In this way language objectifies what would otherwise remain relatively subjective—a factor operative in the process of thinking but not an object of thought—a condition of understanding, but not itself understood. Thus the development of language is a development of self-consciousness. Gesture language is, like conventional language, an instrument of conceptual thinking. The natural signs which compare it are either demonstrative or imitative. The demonstrative consists in some way of drawing attention to an object actually present, or to be found in a certain direction. It is obvious that such indications are not expressive signs unless they form part of a context. This context is supplied by imitative gestures. The imitation consists mainly in tracing the outline of objects in the air, or in copying characteristic features of an action. A deaf mute, it may be, wants a drink of water; he sees neither water nor drinking glass in the room, so that he cannot point to the one nor fetch the other. He takes some one by the hand in order to lead him to the place where water is. The person to whom this appeal is made refuses to move. The deaf mute is perplexed and embarrassed. He adopts the device of pointing to his mouth. This is something more than a practical expedient. It is an expressive sign, at least in the germ, such as is not, so far as I know, used by even the most intelligent animals. But the sign is ambiguous. The person addressed may bring him something to eat instead of something to drink. He is thus driven to define his meaning by a combination of gestures—a context of natural signs. He directs his hand towards his mouth again, but now he curves it as though he held a glass, at the same time imitating the act of drinking. At last he has made himself understood, and a ray of light penetrates his intellectual and moral being. This movement, as it were, transforms him into a human being, whereas his previous pointing had been merely animal language.—*London Mind.*

AMERICAN ANALYST.—$1.00 per year.

There is no place like home

—when *Pearline* is used in it. There is no place about home where *Pearline* can't be used.

Pearline takes the hard work and drudgery out of —keeping a home clean. It is next to having the washing and cleaning done for you, and well done at that.

It washes everything that can be washed. It cleans paint, marble, carpets, hangings—in fact everything cleanable.

It is a luxury in the bath. It is emphatically without harm to person or things. With *Pearline* you have rest; it rests with you to have *Pearline.*

Your Home is probably invaded by peddlers, who claim the stuff they offer is Pearline, "the same as" Pearline, or "as good as" Pearline. IT'S FALSE—Pearline has no equal, and is never peddled. 238 JAMES PYLE, New York.

Buffalo Lithia Water, Spring No. 2, in Bright's Disease, Gout, Stone in the Bladder, and Diseases Generally of Uric Acid Diathesis, Etc., Etc.

DR. WM. A. HAMMOND, of Washington, D. C., Surgeon General U. S. Army (retired), Professor of Diseases of the Mind and Nervous System in the University of New York, etc.

"I have for some time made use of the BUFFALO LITHIA WATER in cases of AFFECTIONS of the NERVOUS SYSTEM, complicated with BRIGHT'S DISEASE OF THE KIDNEYS or with a GOUTY DIATHESIS. *The results have been eminently satisfactory.* Lithia has for many years *been a favorite with me in like cases, but the* BUFFALO WATER CERTAINLY ACTS BETTER THAN ANY EXTEMPORANEOUS SOLUTION of THE LITHIA SALTS, and is, moreover, better borne by the stomach. I also often prescribe it in those cases of CEREBRAL HYPERÆMIA resulting from OVER MENTAL WORK—in which the condition called NERVOUS DYSPEPSIA exists—*and generally with* MARKED BENEFIT."

DR. WM. B. TOWLES, Professor of Anatomy and Materia Medica, in the Medical Department of the University of Virginia.

"BUFFALO LITHIA SPRINGS, No. 2, belongs to the ALKALINE or, *perhaps, to the* ALKALINE SALINE Class, *for it has proved far more efficacious in many diseased conditions than any of the simple* ALKALINE waters.

"*I feel no hesitancy whatever in saying that in* GOUT, RHEUMATIC GOUT, RHEUMATISM, STONE *in the* BLADDER, and in all diseases of URIC ACID DIATHESIS, *I know of no remedy at all comparable to it.*

"*Its effects are marked in causing a disappearance of* ALBUMEN *from the urine. In a* single case of BRIGHT'S DISEASE *of the* KIDNEYS, I witnessed *decided beneficial results from its use, and from its action in this case I should have great confidence in it as a remedy in certain stages of this disease.* In DYSPEPSIA, especially that form of it in which there *is an excessive production of* ACID *during the process of nutrition,* in some of the PECULIAR AFFECTIONS *of* WOMEN, notably in SUPPRESSION of the MENSES, and in CHRONIC MALARIAL POISONING, etc., I have found it highly efficacious."

DR. G. HALSTEAD BOYLAND, late Professor of Surgery, Baltimore Medical College, late Surgeon French Army (Decorated), Member Baltimore Academy of Medicine, Member of American Medical Association.

"In BRIGHT'S DISEASE of the KIDNEYS, ACUTE or CHRONIC, BUFFALO LITHIA WATER, Spring No. 2, is, in my experience, *without a rival,* whether in the PARENCHYMATOUS form or INTERSTITIAL NEPHRITIS. In cases in which the ALBUMEN in the URINE reached as high as 50 per cent., I have known it under a course of this water gradually diminish and finally disappear, at the same time other alarming symptoms were relieved and the sufferers restored to health.

"In STONE in the BLADDER of the RED LITHIC ACID and the WHITE PHOSPHATIC DEPOSIT, the SOLVENT power of this water is *unmistakable.*"

Water in cases of one dozen half gallon bottles, $5.00 f. o. b. here.

THOS. F. GOODE, Proprietor, BUFFALO LITHIA SPRINGS, VA.

TRUE AND FALSE BLOOD-PURIFIERS.

The expression "blood-purifier" is as old as civilization. It occurs in nearly every great language, and while not scientifically accurate, is a significant and useful phrase to convey a series of profound truths. Of late years it has been used, as if it were literally correct, by certain manufacturers of proprietary medicines. They speak of their products as though they were chemicals (and in many cases they are), which could be poured into the circulation and either dissolve out disease or else incorporate health into ailing tissues. It is hardly needful to add that such pretensions are at utter variance with modern pathology and truth.

What is a true blood-purifier? To explain the phrase it is necessary to understand the nature and action of the blood. This, starting from the heart, is first forced through the lungs, where it is put into close and minute contact with the air. The oxygen is absorbed and attacks the worn-out matter floating or dissolved in the blood, and probably, also, some of the normal cells and corpuscles. In case the oxygenation is insufficient, much matter is left that would otherwise be destroyed, and the blood is said to be impure. The process mentioned generates heat and energy, and enables the body to perform its various nervous, muscular, and other activities, all of which, summed up, constitute life. The blood returns to the heart, and thence passes into the circulation. It takes up the worn-out particles of every tissue, and leaves new ones behind. It passes the kidneys, where superfluous and many nitrogenous compounds are strained off, and finally reaches the heart again. In its progress through the arteries and veins it may not take up as much of the worn-out matter as it should. The tissue then begins to enter a diseased condition. It may take up this effete material, but leave none that is new. The result is a wasting away of the part or organ. It may be so poor in quality or deficient in quantity that it only does half work. The person is then said to be anæmic. Sometimes when the oxygen has not destroyed enough cells in the blood, these are deposited in various parts of the body; and so sometimes when the kidneys have not removed objectionable elements, these are similarly deposited by the life-current. When these elements take the form of crystals of uric acid and uric salts, gout and rheumatism occur. When they take the form of lime or calcareous salts, gouty accretions, brittleness of the bones, chronic headaches, stone, and gravel are the painful consequences. All of these are natural products, and result from the natural chemical action of the blood under special conditions. It is easily seen, therefore, that any preparation which claims to merely purify the blood is, on its own showing, worthless. If it did what it claimed, it would be but for a moment. As the blood changes perpetually, it might be normal one minute, and then, under morbid conditions, be impure and poisonous five minutes afterwards. A true blood-purifier is one which destroys or expels the impurities of the blood by putting the vital functions into normal action. The best one known to the medical world to-day is Ayer's Sarsaparilla, a simple scientific preparation of sarsaparilla, yellow dock, and other ingredients, which any one can make for himself who has the chemical knowledge and the scientific apparatus. It acts upon the system at large. It stimulates the nerves, especially those of the secondary system which control the great organs. In this manner it induces the heart to beat with more power, the lungs to inhale more oxygen and exhale more carbonic acid, the kidneys to excrete not more water, but more of the worn-out cells and nitrogenous compounds, the bowels to move more freely and frequently, and the pores to discharge more invisible transpiration. In this manner it destroys the morbid conditions under which the blood and system had become impure, and thus indirectly Ayer's Sarsaparilla purifies both the blood and system. Sunlight and exercise, light diet and aperients, travel and pleasant companions, are all conducive to health. But to change from sickness to a normal condition of the body, and to enjoy the health, strength, buoyancy, and vitality which belong to it, demands, in addition to the factors named, the systematic use of Ayer's matchless preparation.

Exhaustion

Horsford's Acid Phosphate.

The phosphates of the system are consumed with every effort, and exhaustion usually indicates a lack of supply. The Acid Phosphate supplies the phosphates, thereby relieving exhaustion, and increasing the capacity for labor. Pleasant to the taste.

Dr. A. N. KROUT, Van Wert, O., says: "Decidedly beneficial in nervous exhaustion."

Dr. S. T. NEWMAN, St. Louis, Mo., says: "A remedy of great service in many forms of exhaustion."

Mrs. Oldun: "Oh, yes, Pyle's."—*The King's Jester.*

TEA.

Tea which makes the cup that cheers and does not inebriate is an uncertain quantity. It is one of the most difficult articles to judge of, and therefore those who want to be sure of getting the best article for their money would do well to apply to a large and well-known house whose capital is ample, experience large and character established. We know of none who fill this description better than the Great American Tea Company of New York, whose advertisement appears in another column.

IMPORTANT TUNNEL.—The greatest engineering feat in the history of the anthracite coal mining is about to begin. It is the commencement of what will be known as the Jeddo Tunnel, which will be driven for the purpose of draining the flooded mines of Jeddo and Harleigh. It will be constructed from Butler Valley, Pa., to the bottom of Ebervade mammoth vein, a distance of three miles, through solid rock, to be eight feet square in the clear. The scheme of tunneling through the mountain first occurred to John Markle, who is to be president of the company, which will bear the title of Jeddo Tunnel Co., Limited. It will open an inexhaustible supply of coal, and furnish employment for thousands of people for many years to come. It will also serve the double purpose of draining all the collieries in the valley.—*Scientific American.*

ORIGINAL. No. 26.

Breakfast Fruit Cake

BY MARION HARLAND.

1 quart of flour, 2 cups of milk, 2 tablespoonfuls of butter, 1 tablespoonful of lard, ½ teaspoonful salt, 1 quart of strawberries, huckleberries, blackberries or raspberries, ½ cup of sugar, 2 teaspoonfuls of Cleveland's baking powder.

Sift flour, baking powder and salt together, chop in the shortening, stir in the milk with a wooden spoon. The dough should be just stiff enough to handle. Roll into two sheets, line a baking pan with one, put in the berries, strew with sugar, lay on the other sheet and bake. Cut into squares, split and eat hot with sugar and butter.

Use only Cleveland's baking powder, the proportions are made for that.

The leavening power of Cleveland's Baking Powder comes from cream of tartar with soda, nothing else; that is why Cleveland's is perfectly wholesome, leavens most, and leavens best.

The Manufacturers will be pleased to supply members of the Medical Profession with samples of their Pepsin, and with full details regarding digestive strength, if desired.

SEE PAGE 368 FOR VALUABLE OFFER.

WATCHES.

EVERY one wants a watch, and naturally a good watch that keeps accurate time, presents a handsome appearance, and is inexpensive. If such a watch can be found of American manufacture, it is an additional appeal to our patriotism. Just such a watch as this ideal THE ANALYST PUBLISHING COMPANY is enabled to offer as a Premium to its readers. Having some large advertising contracts we have been enabled to procure the movements of the manufacture of the best known American watch factories, namely, the Waltham, Elgin, Hampden and Illinois Watch Companies. These movements are adapted for both ladies' and gentlemen's watches, and are warranted by the makers. These movements have seven jewels, patent lever movement, chronometer balance, patent safety pinion, sunk hard-enameled dial, straight line visible palette, stem winders, hand set; in fact, contain all the latest improvements and can be readily cleaned or repaired by any ordinary good watchmaker. They can be regulated to run as close as any movement.

It is needless to say that to case these movements in solid gold cases would make them too expensive, yet they are cased in what are known as gold filled or stiffened "Ladd" cases, and are warranted to be 14 karat gold, made from two sheets of 14 karat gold overlaying fine composition metal, with regular jointed caps, covers and bezels, and to wear at least five years. They are not plated, nor rolled gold, but actual 14 karat gold cases, thin of course, but stiffened and strengthened by being filled with this fine composition metal. They are finished in the same manner, engine turned and engraved as solid gold watches, and wear and look just the same. No one but an expert can tell them from a solid gold watch. These watches are made both open face and hunting case style, in gentlemen's or ladies' sizes. For gentlemen we recommend plain engine-turned cases; for ladies, a handsomely engraved case.

How to Obtain One of these Watches.

These watches are not to be purchased from us at any price. Send us a club of 25 subscribers to the AMERICAN ANALYST, and $25, the regular subscription price, and one of these watches (your choice of style and size) will be immediately forwarded, post-paid and registered, to your address. You need not wait until you have your 25 subscribers all together, but forward them as you get them and they will be credited to you, and when the number is complete the watch will be sent. A subscription for two or three years will be counted as two or three subscribers.

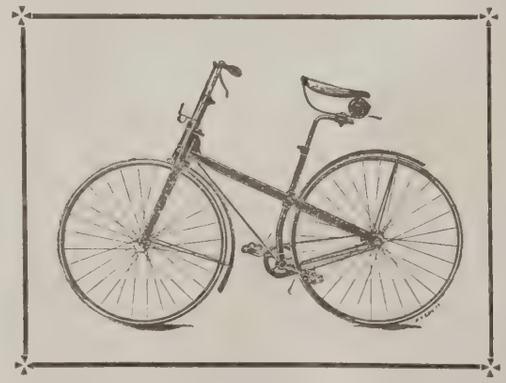
As these watches are retailed by jewelers at not less than $25, it will be seen that we are offering a real premium with the sole object of increasing our circulation, and that by taking advantage of our offer any one can obtain a good, reliable and handsome watch without cost. As the number of these watches at this price is limited, it is advisable to take steps at once to procure a bargain.

THE ANALYST PUBLISHING CO., 19 PARK PLACE, NEW YORK.

BICYCLES

GIVEN AWAY TO BOYS AND GIRLS!

AN OPPORTUNITY OPEN TO ALL.



The Analyst Publishing Company being desirous of largely increasing their subscription list, will furnish every one with a beautiful Safety Bicycle, ABSOLUTELY FREE, in return for a few hours' canvassing.

To every boy and girl who secures 75 subscribers for the American Analyst at $75, we will give a splendid

$40.00

NONPAREIL

SAFETY BICYCLE.

These bicycles are adapted in size to boys, but are strong enough to carry a man. A boy's bicycle should be a strong one. They are manufactured by the OVERMAN WHEEL CO., the makers of the celebrated VICTOR Bicycle, and have the full guarantee of the makers.

The following is a brief description of the NONPAREIL SAFETY; 26-inch wheels; ball bearing all around, including pedals; solid crescent rims; double tangent spokes; three-fourths inch tires; cranks, three throw, $4\frac{1}{4}$ to $5\frac{3}{4}$ inches; guards to both wheels; tool-bag, oiler and wrench. Finished in bright enamel, all exposed metal heavy nickel-plate on copper.

In selecting these machines as a premium, we have disregarded cheapness and selected a Bicycle which is serviceable, and the makers of which have an established reputation for building the best Bicycle that money, machinery and brains can produce. We are actually furnishing the Bicycles and Papers at less than cost, but hope by stimulating active and successful canvassing, and thus enlarging our subscription lists, to make an eventual profit. We positively guarantee these bicycles to be just as here represented. They will be shipped by express f. o. b. in New York.

Subscription orders must be made out plainly and legibly, and sent as fast as secured, addressed to

THE ANALYST PUBLISHING CO., 19 Park Place, New York.

ONE YEAR FREE.

If you will send us the addresses of Twenty-five Ladies in your neighborhood to whom we can send sample copies of the **AMERICAN ANALYST,** we will send this paper to you free for One Year; or, for Fifteen names, Six Months; or, for Ten names, Three Months. TABASCO PEPPER SAUCE,

OR LIQUID PEPPER.

Is simply the Pulp of the Ripe Pepper Extracted by Pressure.

The seed of this Pepper was obtained from Central America, and by careful cultivation in Louisiana for many years has been so improved in strength, flavor and aroma, as to have become a new variety of Red Pepper, superior to all others. The pulp is so handled as to retain all the flavor, strength, aroma and color of the ripe fruit, and to keep unimpaired in any climate. It excites the appetite, promotes digestion, and is pronounced by connoisseurs to be the finest condiment in the world. For medicinal purposes it recommends itself by its purity, strength and diffusible form.

Manufactured by E. McILHENNY'S SON,

NEW IBERIA, LA.

For Sale by all Wholesale Grocers.

NATRONA BI-CARBONATE OF SODA.

ABSOLUTELY PURE.)

The nature of the raw material from which NATRONA BI-CARBONATE OF SODA is made—viz., kryolith, a mineral containing *pure sodium*—insures a purity and uniformity of product which cannot be obtained from any other known material. In making BI-CARB. SODA from any other raw material, the use of sulphuric acid is a necessity, but none is used in any part of the process of making NATRONA BI-CARB.; hence its entire freedom from the slightest trace of arsenic, which is always present in ordinary soda. Its absolute purity and entire freedom from all traces of *sulphate of soda*, common salt and other impurities, render NATRONA BI-CARB. NEARLY TASTELESS, and being bolted through the finest bolting-cloth, insures the finest stage of division.

To these indisputable facts the attention of CONSUMERS of soda is specially called. They are IMPORTANT, and should influence both those who use and those who sell soda, to buy and sell NONE BUT THE BEST.

The NATRONA BI-CARB. Soda is kept in stock by almost every wholesale druggist and grocer throughout the United States, of whom it may be ordered.

Natrona Bi-Carb. Soda is unequaled by any other brand of English or American Manufacture.

INSTRUCTIONS TO SUBSCRIBERS.

The Names of all Subscribers are registered as soon as received, and paper is always promptly forwarded.

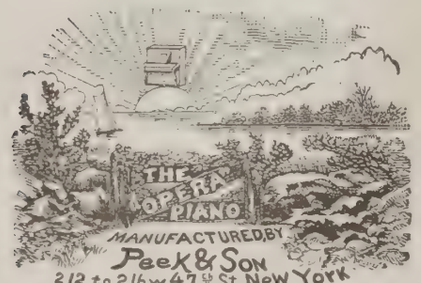
Postage.—The postage to all parts of the United States and Canada is paid by the publisher.

Remittances of small sums may be made with comparative safety in ordinary letters. Sums of one dollar or more must be sent by registered letter or P. O. money order, otherwise we cannot be responsible for same. Silver must not be sent in a letter.

Postage Stamps will be received for the fractional part of a dollar, and in any amount when it is impossible for patrons to procure bills, but you must send one or two-cent stamps only.

SUBSCRIPTIONS.—The AMERICAN ANALYST will be sent one year to any subscriber for ONE DOLLAR. New subscriptions can begin at any time.

We Stop the Paper at the expiration of the time paid for unless a renewal of subscription is received. Those whose subscriptions have expired must not expect to continue to receive the paper unless they send the money to pay for it.



Change of Address.—Subscribers wishing their addresses changed must invariably give their former as well as new address.

Missing Numbers.—It occasionally happens that numbers of our paper sent to subscribers are lost or stolen in the mails. In case you do not receive any number when due, write us a postal card and we will cheerfully forward a duplicate of the missing number.

Most Important of All.—In every letter that you write us, never fail to give your full address, plainly written—name, post-office, County and State.

THE INCANDESCENT LAMP DECISION.

About a fortnight ago Mr. Edison gained what appeared to be a conclusive decision in his favor, in the shape of an injunction prohibiting other electrical companies from making and selling incandescent lamps, the United States courts having recognized him as the inventor and patentee of these instruments. On July 22, however, in the United States Circuit Court, Justice Wallace, in chambers, granted a six months' stay of the injunction pending an appeal by the defendants in the case, who meanwhile are placed under bonds to the amount of $50,000. In moving for the stay several affidavits were presented, replete with instructive historical facts relating to this peculiar branch of the lamp industry, but want of space prevents our placing them before the readers of the AMERICAN ANALYST. An interesting synopsis of them is given in the *Electrical Review*, which journal also discusses them briefly in its editorial columns as follows: "Judge Wallace has ordered a suspension of the injunction in the lamp case pending an appeal. This will leave the commercial features of the lamp industry substantially in *statu quo*. The value of the decision in favor of the plaintiff will be the influence it may exert on the Appellate Court. The reasons influencing the order were the delay the plaintiff had made in bringing its suit and the doubtful character of the patent on its face, which invited competition and led to the investment of a great amount of capital. If the injunction were permitted to go into immediate effect, the public would be affected by the necessary interruption of many existing lighting plants, and a great number of men would be thrown out of employment. He thought the suspension of the injunction for six months was not unreasonable, in view of a delay of five years in bringing suit. The operation of this order will be of great present value to the defendant company. Much might be said for or against the order. The court having once declared the patent sound and that infringement existed, it would seem that the consequences of the infringement should be borne irrespective of any embarrassment that might ensue. On the other hand, where a clouded title led people, who acted under the best light they could get on the patent, to invest large amounts of capital, and where they were permitted to build up a large business for five years before being called to task, strong grounds for indulgent treatment exist. Judge Wallace's remarks that there is a 'fair doubt' whether his decision will be sustained will tend to mask the effect it would have in the construction of the Appellate Court, and adds another element of doubt to the ultimate issue. The order for the stay suspends the operation of the injunction so far as regards the manufacture and sale of lamps by the United States Company to be used in connection with the dynamo machines, including those already sold and those which may be sold in the future."

WOMEN IN 1893.

The fair sex is to be well represented in the official councils of the Columbian Exposition, at Chicago, in 1893. Illinois has not only given women a representation of eight members upon the State Commission, but has a special appropriation of $80,000 for their separate use—placing ten per cent. of the State appropriation at their absolute disposal. The Illinois State Board convenes this month, and the women's work will at once begin. No other State has made a special appropriation for this purpose, but Indiana has been in all other respects as generous in official recognition of women as Illinois. Colorado comes close after and has also given women a place on her State board. In addition these lady Commissioners are permitted the privilege of putting two additional women in the field to canvass the State in the interest of the Board, and a third to collect the native flora. Massachusetts has appointed three women upon a State Commission of five. Rhode Island has four women in a State Commission of sixteen members, and a lady has been elected Treasurer and Secretary. It may be mentioned that a woman is now searching the Patent Office at Washington for records and models of women's inventions from the earliest history of America. Pennsylvania has recognized the lady managers as State officers upon its Commission. The silk producing industry will undoubtedly make a fine showing through the Woman's Board, as the lady manager for Pennsylvania has been for years the President of the largest silk growing association in the United States. Many women in Georgia and California are also engaged in the silk industry. In the State of Washington the lady managers are ex-officio members of the State Board. In every instance, excepting the three special appointments in Colorado, the lady Commissioners receive no salaries, only their expenses when engaged in the actual service of the Commission being paid by the State. It is also announced that Mexican women will receive official recognition from Mexico's World's Fair Commission; this, in view of that country's extreme conservatism and of the almost Oriental limitations of the privileges of its women, is something quite remarkable and unexpected.

THE COMET FINDER.

The *Science News* characterizes as one of the most ingenious scientific hoaxes ever perpetrated, the description of an alleged automatic "comet finder" attributed to the inventive genius of Professor Barnard of the Lick Observatory, the action of which was said to be dependent upon the varying electric resistance of the element selenium under the action of light. Originally appearing last Spring in a San Francisco daily newspaper, it was written with such skill, and with all the details of the apparatus described in such a plausible manner by one evidently thoroughly familiar with the principles of physics and astronomy, that it was particularly well calculated to deceive—as, in fact, it did—nearly every scientific periodical in the country, although a close examination of the article would have shown at once the absurdity of the story. A letter from Professor Barnard, exposing the hoax, states that he considers it one of the most remarkable ever gotten up on an astronomical subject, and that it was originated by a young man of remarkable ability—as, indeed, he must have been to have succeeded in deceiving so many persons familiar with such matters. Professor Barnard's "comet finder" will have to be classified hereafter with the "moon hoax" of some half a century ago, and other products of a too lively and indiscriminating scientific imagination.

WHAT IS ELECTRICITY?

A PROBLEM LIKELY SOME DAY TO BE SOLVED.

A highly interesting and instructive lecture on electricity was delivered May 20 before the American Institute of Electrical Engineers, at Columbia College, by Nikola Tesla. The entire discourse is published in the *Electrical Review* of July 11, oocupying more than seven pages of the valuable space of our enterprising contemporary, from which we condense the subjoined significant sentences: Nature has stored up in the universe infinite energy. The eternal recipient and transmitter of this infinite energy is the ether. The recognition of the existence of ether, and of the functions it performs, is one of the most important results of modern scientific research. The mere abandoning of the idea of action at a distance, the assumption of a medium pervading all space and connecting all gross matter, has freed the minds of thinkers of an ever-present doubt, and, by opening a new horizon—new and unforeseen possibilities—has given fresh interest to phenomena with which we were familiar of old. It has been a great step towards the understanding of the forces of nature and their manifold manifestations to our senses. It has been for the enlightened student of physics what the understanding of the mechanism of the fire-arm or of the steam engine was for the barbarian. Phenomena upon which we used to look as wonders baffling explanation we now see in a different light. The spark of an induction coil, the glow of an incandescent lamp, the manifestations of the mechanical forces of currents and magnets are no longer beyond our grasp. Instead of the incomprehensible, as before, their observation suggests now in our minds a simple mechanism, and although as to its precise nature all is still conjecture, yet we know that the truth cannot be much longer hidden, and instinctively we feel that the understanding is dawning upon us. We still admire these beautiful phenomena, these strange forces, but we are helpless no longer. We can in a certain measure explain them, account for them, and we are hopeful of finally succeeding in unravelling the mystery which surrounds them. Of all the forms of nature's immeasurable, all-pervading energy, which, ever and ever changing and moving, like a soul animates the inert universe, those of electricity and magnetism are perhaps the most fascinating. The effects of gravitation, of heat and light we observe daily, and soon we get accustomed to them, and soon they lose for us the character of the marvelous and wonderful: but electricity and magnetism, with their singular relationship, with their seemingly dual character, unique among the forces in nature, with their phenomena of attractions, repulsions, and rotations, strange manifestations of mysterious agents, stimulate and excite the mind to thought and research. What is electricity, and what is magnetism? These questions have been asked again and again. The most able intellects have ceaselessly wrestled with the problem; still the question has not as yet been fully answered. But, while we cannot even to-day state what these singular forces are, yet we have made good headway towards the solution of the problem. We are now confident that electric and magnetic phenomena are attributable to ether; and we are, perhaps, justified in saying that the effects of static electricity are the effects of ether under strain, and those of dynamic electricity and electro-magnetism effects of ether in motion. But this still leaves the question, as to what electricity and magnetism are, unanswered. First, we naturally inquire, What is electricity, and is there such a thing as electricity? In interpreting electric phenomena, we may speak of electricity or of an electric condition, state or effect. If we speak of electric effects we must distinguish two such effects opposite in character, and neutralizing each other, as observation shows that two such opposite effects exist. This is unavoidable, for in a medium of the properties of ether, we cannot possibly exert a strain, or produce a displacement or motion of any kind, without causing in the surrounding medium an equivalent and opposite effect. But if we speak of electricity, meaning a thing, we must, I think, abandon the idea of two electricities, as the existence of two such things is highly improbable. For how can we imagine that there should be two things, equivalent in amount, alike in their properties, but of opposite character, both clinging to matter, both attracting and completely neutralizing each other? Such an assumption, though suggested by many phenomena, though most convenient for explaining them, has little to commend it. If there is such a thing of electricity, there can be only one such thing, and, excess and want of that one thing, possibly, but more probably its condition, determines the positive and negative character. The old theory of Franklin, though falling short in some respects, is, from a certain point of view, after all, the most plausible one. Still, in spite of this, the theory of the two electricities is generally accepted, as it apparently explains electric phenomena in a most satisfactory manner. But a theory which explains better the facts is not necessarily true. Ingenions minds will invent theories to suit observation, and almost every independent thinker has his own views on the subject. What, of all things, the existence of which we know, have we the best reason to call electricity? We know that it acts like an incompressible fluid; that there must be a constant quantity of it in nature; that it can be neither produced nor destroyed; and what is more important, the electro-magnetic theory of light and all facts observed teach us that electric and ether phenomena are identical. The idea at once suggests itself, therefore, that electricity might be called ether. Nothing would seem to stand in the way of calling electricity ether associated with matter—bound ether; or, in other words, that the so-called static charge of the molecule is ether associated, in some way with the molecule. Looking at it in that light, we would be justified in saying that electricity is concerned in all the molecular action. Now, precisely what the ether surrounding the molecules is, wherein it differs from ether in general, can only be conjectured. It cannot differ in density, ether being incompressible; it must, therefore, be under some strain or in motion, and the latter is the more probable. To understand its functions it would be necessary to have exact idea of the physical construction of matter. But of all the views of nature the one which assumes one matter and one force, and a perfect uniformity throughout, is the most scientific and likely to be true. An infinitesimal world, with the molecules and their atoms spinning and moving in orbits in much the same manner as celestial bodies, carrying with them ether, which is probably spinning with them—in other words, carrying with them static charges—seems to my mind the most probable view; one which in a plausible manner accounts for most of the phenomena observed. The spinning of the molecules and their ether sets up ether tensions or electrostatic strains; the equalization of ether tensions sets up ether motions or electric currents, and the orbital movements produce the effects of electro and permanent magnetism. About fifteen years ago Professor Rowland demonstrated a most interesting and important fact, namely, that a static charge carried around produces the effects of an electric current. We can conceive lines or tubes of force which physically exist being formed of rows of directed moving molecules; we can see that these lines must be closed; that they must tend to shorten and expand, etc. It likewise explains in a reasonable way the most puzzling phenomenon of all, permanent magnetism, and, in general, has all the beauties of the Ampere theory without possessing the vital defect of the same, namely, the assumption of molecular currents. Without enlarging further upon the subject I would say that I look upon all electrostatic current and magnetic phenomena as being due to electrostatic molecular forces. The possibilities which are opened by modern research are so vast that even the most reserved must feel sanguine of the future. Eminent scientists consider the problem of utilizing one kind of radiation without the others as a rational one. In an apparatus designed for the production of light by conversion from any form of energy into that of light such a result can never be reached, for no matter what the process of producing the required vibrations, be it electrical, chemical or any other, it will not be possible to obtain the higher light vibrations without going through the lower heat vibrations. It is the problem of imparting to a body a certain velocity without passing through all lower velocities. But there is a possibility of obtaining energy, not only in the form of light, but motive power and energy of any other form, in some more direct way from the medium. The time will be when this will be accomplished, and the time has come when one may utter such words before an enlightened audience without being considered visionary. We are whirling through the endless space with an inconceivable speed, all around us everything is spinning, everything is moving, everywhere is energy. There must be some way of availing ourselves of this energy more directly. Then, with the light obtained from the medium, with the power derived from it, with every form of energy obtained without effort, from the store forever inexhaustible, humanity will advance with giant strides. The mere contemplation of these magnificent possibilities expands our minds, strengthens our hopes, and fills our hearts with supreme delight.

FLORIDA PHOSPHATES.

EXTENSIVE DEPOSITS OF VALUABLE FERTILIZERS IN FLORIDA.

An expedition of the Geological Survey has just returned from Florida, whither it was sent to investigate the newly discovered phosphate beds in that State which are undoubtedly the most wonderful deposits of their kind in the world. For a period covering so so many millions of years that no one would ever think of trying to reckon the time, these beds were being formed under the sea by billions of generations of mollusks and other shellfish, big and little, which died and added their limy remains to the steadily increasing deposits. Thus, when the ocean retreated, banks of lime appeared, innumerable sea fowl occupied them for roosting purposes, and their manure infiltrated the shelly substance, This manure contained in large quantities phosphoric acid, which took the place of carbonic acid in the lime and transformed it into a phosphate of that substance, as the chemists call it. Now, it happens that phosphoric acid is one of the elements most essential to vegetable reproduction, because it enters so largely into the composition of plants. Seeds are more than half made of it. A cow at pasture for one summer will take away from the land fifty pounds of this material in the shape of veal and milk. Therefore the soil must be continually resupplied with it, and hence the great value of the phosphate of lime derived from fossil deposits. Although the Florida beds were only discovered two years ago, the expedition reports that a large part of the State is already transformed into a veritable mining camp. For two hundred miles through the north and northwest counties quarrying for the substance is, going on, mines are being opened, and the product is being prepared for shipnment. Real estate and other sharks are active, and fortunes are being made and lost; but there seems to be no doubt of the fact that the finding of this new wealth is a great thing for the flowery peninsula. In the region referred to it is the rock phosphate that is found—the solid substance—in a layer that is as much as fifty feet thick in places covered over with the sand which form the surface soil to the depth of from two to twenty feet. Of course

people in Florida have known of the existence of this curious limy deposit for ever so long. Over a great part of the State they could not dig very far without coming upon it. But it is only a little while ago that some person gifted with the sublime curiosity that approaches genius thought of having the stuff analyzed. Then it was that numerous "cracker" residents learned how they had been living on top of what might as well have been a gold mine, while dining upon the hog and hominy of ignorant privation. The method adopted in working these deposits is, first, to sound the ground by driving into it at intervals of a few feet a long iron rod with a sharpened point. When the phosphate bed is reached, the rod is withdrawn and a stake is stuck in its place with figures on it indicating the number of feet of depth at which the strike has been made. In this way a district of more or less extent is "rodded," and operations are begun by clearing away the surface soil in the most promising spots and quarrying out the material. The process is like any other open quarrying, the blast being supplemented by the pickax and the shovels. Before the substance is ready for shipping, it is dried in kilns in order to free it from all moisture, after which it is put on cars and forwarded by rail to Fernandina, Tampa, Punta Gorda, and some to Alanta, Ga. At these points it is loaded aboard vessels bound for Europe or for New York, Baltimore, or other American ports. England is a large buyer of phosphate. After arriving at its destination, say Baltimore, the material is ground into a fine dust and treated with sulphuric acid, so that it is transformed into a powder which would be termed by a chemist an "acid phosphate." This powder is then mixed with other ingredients so as to compose fertilizing preparations for various purposes. The fruit grower wants one mixture, the vegetable farmer another, and so on. However, the ingredients mentioned are either nitrates, the nature of which will be presently described, or refuse from packing works, in the shape of bones, horns, blood, and all manner of corruption, reduced by desiccating processes to pulverized inoffensiveness. Elsewhere in Florida great beds are found of phosphates in a different condition. In the middle of the State, over an area covering hundreds of square miles, the soil is underlaid by a stratum as much as fifteen feet thick in some places of the same material in the shape of pebbles densely strewn in a whitish clayey matrix. Buried in this layer are discovered great masses of the remains of huge animals extinct for ages, particularly sharks, which were doubtless seventy or eighty feet in length. One gets some notion of the swarm of these ferocious giants of the deep that existed in that antediluvian age from the finding of their great teeth, each longer than a man's hand, in the phosphate, as thickly distributed as plums in a puddling. In the same deposits are found countless bones of the mastodon, the megatherium, the elephant, the hog, the horse, the muskrat, etc. They are immense graveyards of ages long gone by, preserving for the contemplation of man the remains of the mighty beasts and fishes. These phosphate "land pebbles," as they are called, are supposed to have been originally derived from the rock deposits, being fragments washed to their present shape by water; but no one knows positively. The nitrates, of which mention has been made, are obtained largely from Chili, where the supply is practically controlled by Col. North, the "Nitrate King," who is such a great friend of the Prince of Wales. They are simply deposits of nitrate of soda in the beds of lakes long ago dried up, which originally contained in solution large quantities of that material. At present it is simply necessary to dig it up, put it through suitable processes, and ship it at so much a ton, for fertilizing purposes. When a lake receives the flow of a great watershed and has no outlet, except by evaporation, its water naturally accumulates and precipitates on the bottom the chemical elements filtered into it from the soil around about. Hence the nitrate deposits referred to. Bird manure, as has been said, contains a great percentage of phosphoric acid, and hence its wonderful value as a fertilizer. So well was this appreciated centuries ago that the Incas of ancient Peru declared death as the punishment for any one who killed even one of the birds which deposited guano on the islands off their coasts. Of late years many of these guano islands have been stripped of their precious material, and before long none of it will be left, although in places it was an hundred feet in depth, being composed of droppings of flamingoes, divers, penguins, and other sea fowl during countless generations, together with their carcasses, and the excrement of seals, sea lions, and marine animals of various sorts innumerable. Many considerable deposits of bat guano have been found in caves in various parts of the United States, made up of the dropping and bones of these animals, and from such beds fertilizing supplies have been drawn; not to mention the use made of them during the war as mines for the production of saltpetre, from which to manufacture gunpowder.

ECLIPSES IN HISTORY.

HOW DATES ARE DETERMINED BY AID OF THE SUN AND MOON.

Every reader of *Vom Fels zum Meer*, says Prof. Schubert in that journal, must be familiar with the important role played by the moon in the fixing and determining of dates, among the people of earlier civilization; the regularity of its rotation, and the consequent possibility, by calculating backward, of determining the dates of new or full moon at any period, however remote, being important aids in determining the precise date at which given historical events occurred. But the chronological value of the moon rests not merely on the unbroken regularity of its tireless course and change of phases; the periodically recurring eclipses of the sun and moon being calculated backward, events of ancient history can have their correct dates assigned to them with absolute exactitude. It occurs on an average once to twice a year that the full moon wholly or partially enters the pointed conical shadow which the sun continually projects from the earth on the side furthest from it, a hundred thousand miles into space. At such times we see the shadow of the earth thrown upon the moon's disc, which is then wholly or partially eclipsed. This phenomenon is visible simultaneously from all parts of the earth where the moon is above the horizon. A still more remarkable phenomenon is the eclipse of the sun. This occurs at new moon, when the point of the shadow which the sun projects from the moon is thrown upon the earth. This shadow is also a pointed cone projecting into space from the side of the moon furthest from the sun. But since the moon is smaller than the earth, it is impossible that it can envelope it wholly in its shadow. In fact, the point of the shadow covers only a narrow region of the earth, from which region alone the sun is wholly eclipsed. In the immediately surrounding region the sun is only partially eclipsed, and in more remote regions not at all. Total eclipses of the sun occur on an average about three times in four years, but a total eclipse for any given region of the earth does not occur oftener than once in two hundred years. It is, hence, possible, when an eclipse of the sun is described as occurring in connection with some remote historical event, and the hour of the eclipse is mentioned, as is sometimes done, to fix the period of the occurrence with exactitude and thereby materially facilitate historical research. The first to concern himself with the backward calculation of eclipses as an aid to chronology was the French astronomer, Pingre, who, at the close of the last century, calculated the dates of the eclipses which had occurred, or would occur, in civilized regions from 1000 B. C. to 2000 A. D. A work of this magnitude proved too much for one man, and the calculations were generally faulty. To remedy this and provide reliable data for historical research, the work was again taken in hand by the Viennese Astronomer Royal, Professor von Oppolzer, whose work, "Kanon der Finsternisse" (Laws of Eclipses), was published in 1887. Oppolzer himself worked out the plan and calculations and detail, and was assisted in his labors by ten astronomers, whom he paid from his own purse. This work, which fixed the date of 8,000 eclipses of the sun and 5,200 eclipses of the moon, extending over a period from 1207 B. C. to 2163 A. D., filled 242 thick folio volumes with its calculations. The published "Kanon" gives the results only on 376 pages of large quarto, to which are added 160 maps of the world, on which are indicated the zones of visibility of all the total eclipses, so that a mere glance at the map is sufficient to determine the date of any given total eclipse. It may be asked here: how was it possible to foretell eclipses in the old days before astronomy was reduced to science? This is explained by the fact that even in the earliest ages the dates of eclipses, whole or partial, were recorded, and evidence thus secured that after every 223 revolutions of the moon, that is, after every 19,756 days eclipses recur in the same order. These eclipse periods were called "Saros" by the Greeks who undoubtedly got them from the Chaldeans. There are grounds, however, for concluding that this period was known to the Chinese 3,000 years before the birth of Christ, and that the ancient Hindoos foretold eclipses by the same calculation. This method is not, however, absolutely trustworthy, furnishes no precise details, and in forecasting eclipses of the sun, leaves unanswered the important question whether the eclipse will be total or partial, or in what precise region it will be visible. But, since we have not only in Greek and Roman writings, but also in Chinese, Indian, and Arabian writings, records of a number of eclipses with their attending circumstances, it is often easy to identify one of them with one indicated in the "Kanon." In illustration of the influence upon historical data of this ability to calculate past eclipses, it will suffice to point to two famous examples: The first, that of the oldest recorded eclipse, which occurred in China 4,000 years ago; the second that of the eclipse in Jerusalem during the Crucifixion. We have an account of the first in the Chinese book "Schuking," according to which an eclipse took place in the early morning in the last month of harvest in the fifth year of the reign of the Emperor Tschung-hang. From other sources we learn that the Emperor Tschung-hang undoubtedly reigned in the twenty-second century, B. C. And Oppolzer determined that the only eclipse of the century which would apply, took place on the 22d October, 2137 B. C. With regard to the second example, Eusebuis says that Christ suffered in the nineteenth year of Tiberias, and we learn from Greek records that in this year the sun was darkened, Bithynia shaken, and the greater part of Nicea laid in ruins. Phlegon narrates that a total eclipse of the sun, which lasted from the sixth to the ninth hour occurred in the reign of Tiberias "during full moon." Paulus Diaconus says the same, and adds that neither the moon nor the clouds intervened to produce it, and that it occurred on the 14th day of the month. Now an eclipse of the sun at full moon is an impossibility. Nevertheless, on reference to the "Kanon" we find, that a total eclipse of the sun, and the only one that occurred in that region between eight years before our reckoning and 59 A. D., took place on Thursday, the 24th November, 29 A. D. This is not reconcilable with the scriptural account of the Crucifixion which places it at the time of the Jewish Easter. On reference to the "Kanon" we find, however, that on Friday, the 3d April, 33 A. D., there was an eclipse of the moon, visible at Jerusalem. There is, hence, little room for doubt that the historians confused the two events and that the eclipse of the moon was the phenomenon which signalized the Crucifixion.

AN AMERICAN DUCHESS.

THE LONDON HOME OF THE DUCHESS OF MARLBUROUGH.

No. 3 Carlton House Terrace, lately bought by the Duchess of Marlborough, was for many years the residence of the late Lady Brownlow, whose hospitality therein dispensed is still most pleasantly remembered. It is one of the largest of the spacious mansions that form the terrace, and impresses one the moment the entrance doors are passed with a sense of quiet repose and dignity. The wide vestibule and hall are softly carpeted and warmly colored, not a footstep breaks the silence, not an inharmonious note jars upon the nerves. Against the dull crimson walls a collection of arms and weapons is artistically arranged in a trophy *motif;* the wide staircase ascends at the back, and is broken half way by a broad landing. In Lady Brownlow's time the second short flight of stairs gave immediate access to the morning room, but the Duchess of Marlborough has altered this inconvenient arrangement by making the old boudoir into a large square ante-chamber, divided from the staircase by six handsome columns of *verde antique* marble. Opening from this is the new room built by the Duchess for her own special sanctum, to reach which you go down three or four steps, easily shut off when desirable by portieres and glass doors. Truly a gem of a room, replete with a thousand charming artistic and historic souvenirs and bearing the stamp of individuality bestowed by the constant presence of its mistress. The proportions are lofty and pleasing; the walls are hung in brocade of a soft, brilliant, yet pale green shade, supported by a low dado of white enameled wood. One broad window opening to the floor is draped in a similar texture, and gives access to a miniature conservatory, all lined with palms and tropical ferns and made gay and lovely with the choicest flowers, orchids especially, these being the Duchess of Marlborough's favorite exotic, and any one familiar with the beauty and rarity of the Blenheim orchids will at once realize the gorgeous effect of color and form thus attained. Birds have their homes here, too, singing in their cages merrily enough, and lesser flowers bloom on all sides. "Oh, indeed, yes!" her Grace says with a bright smile, "I do love this little room; it is my very own, you see, and here I am never disturbed. My flowers and my birds make it very bright and homelike, and it is not too large to be thoroughly comfortable and cosey." The decorations of this little salon are Louis XVI. in style, the marble chimney-piece being a particularly fine example of French workmanship of that period, though showing strong evidences of the influence of the English brothers Adams in the design and execution. The centre jamb has an interest of its own, as it was taken from one of the original mantel-pieces at Blenheim Palace; the pure, severe lines of the bold half-relief sculptured figures are neither concealed nor half hidden by draperies, an innovotion too often adopted without satisfactory results. Above the narrow shell hangs an antique mirror framed in ornate gilt moulding, and above this again a most beautiful portrait, painted by Sir Joshua Reynolds, of one of the Churchill ancestresses. The wide hearth is tiled in marble, and on the low fire-dogs burns that most cheery of all fires, old, well-seasoned oak logs. On the walls hang a few rare and valuable pictures; one of a little maiden, by Sir Joshua, in a quaint green frock and a high conical head dress; near to this is a beautiful landscape, and beneath it a group of three water-color drawings are full of pathetic interest, not only on account of their intrinsic merit, but because they once belonged to the Empress Eugenie, and were special favorites of hers in the happier days of her checkered career. Two beautiful examples of old faience hang above a low *chaise-tongue;* both are relics from the famous Sellier sale. A tiny, slim-legged marqueterie table stands before the fire, holding a pretty collection of silver toys, and at right angles with the smaller window is placed a commodious and delightful escritoire, furnished with every luxury and convenience, including a telephone and electric bell, that the heart of the most *exigeant* scribbler could desire. With a sigh of regret you leave this delightful boudoir, and passing through the glass doors and up the short flight of steps enter the drawing-rooms on the left. These open one from the other, and form a stately suite when all *en grande tenue.* The spaciousness of the proportions is what most strikes you, and the loftiness of the ceilings, finished in half-cove, ornamented in gold on a cream-white ground. The design is very elaborate, being a replica of one of the ceilings at Versailles of Louis XVI. period. The walls are hung in rich satin damask of that rare and very beautiful shade known as *bouton d'or*—that subtle gleaming tint which catches a thousand golden lights and reflections as the sun strikes across it. Upon this exquisite background, filling all the larger spaces, are very choice old Flemish tapestries, supplemented here and there by some artistic gem in bronze or some veritable "old master," sent from the Blenheim gallery. A fine bust in green bronze, standing in one corner on a slender marble pedestal, at once arrests the eye, not only as a superior work of art, but also as a speaking, life-like presentment of *Le Grand Monarque*—Louis XIV. A large mirror of old French workmanship hangs above the narrow marble mantelshelf, in itself an exceptional specimen of eighteenth century stone carving; and on either side are candelabra groups, veiled in soft-hued silks, that diffuse the cool white rays of the electric light. The furniture is ornate and florid, the elaborate gilt mounts setting off effectively the dainty brocades, flowered silks, and delicate satins of varying hues, which seem almost too fairy-like for daily use. Here, too, on every side flowers hold undisputed sway, adorning quaint console tables and graceful ormulu cabinets, growing in pots or thrown carelessly into antique vases and great crystal bowls. The air is heavy with the sweet perfume, and on every hand the eye is gratified by their graceful forms and vivid coloring—for the Duchess of Marlborough has the inherited love of her nation for these children of nature. "I cannot live without flowers," says her Grace. "You know what a necessity they are to American women. We are accustomed to their influence from our childhood—just as we are accustomed to bright sunshine and blue skies. I am a true American in my love for them. Life without flowers would not be life to me—certainly not life worth living!" Opening from this stately yellow salon is the second drawing-room, with its three long windows looking out upon St. James' Park, a room full of the most delicious things, over which one would like to linger for hours. The walls and draperies are of a bright positive "flame color" damask, a brilliant, peculiar shade with a gleaming copper sheen upon its surface. The color and design are Blenheim heirlooms, and its resuscitation is due to the Duke of Marlborough having unexpectedly discovered a torn and tattered fragment of the original damask on an old chair, which so pleased his artistic taste that he immediately had the pattern and fabric copied and reproduced. The pictures that adorn this inner drawing-room are of themselves a liberal education, being for the most part original Rubenses, brought from the Blenheim collection. Truly a charming home, well worthy of the charming hostess who greets you with such unaffected courtesy and cordiality. The Duchess of Marlborough is a beautiful woman, tall and extremely graceful, with a touch of gold in the abundant brown hair that grows low upon the broad white forehead, expressive hazel eyes, and decidedly marked eyebrows. The charm of her face lies, however, in its ever changing expression, in the light that comes and goes in her eyes, in the smile that plays about her mobile lips, and that reminds you irresistibly of Cabanel's immortal "Marguerite," and as a natural sequence of Mme. Christine Nilsson, who inspired the French painter with his ideal of Goethe's unfortunate heroine. It is now nearly three years since Mrs. Louis Hammersley, of New York, became the Duchess of Marlborough, and came to England to make her home at Blenheim, and to restore that historic palace to something of its former beauty and grandeur. She has the peculiar charm of manner, voice, and inflection that render her so unlike other people, and so especially different from what we have wrongly come to accept as the "typical American woman." In conversation her Grace is amusing and brilliant, an accomplished linguist, and an appreciative if somewhat desultory, reader. Her views on all social topics are well thought out and well expressed, and her digest and exposition of the peculiarities and differences existing between the national characteristics of Englishmen and Americans is at once witty, shrewd and original. She is also an enthusiastic lover of art, and a connoisseur and critic of more than ordinary ability and acumen. Blenheim is, par excellence, the home of her choice and selection, and on the rehabilition of that historic spot she has lavished her wealth unsparingly." *The London Queen.*

MIND READING.

A KENTUCKY YOUTH WITH A WONDERFUL GIFT.

A new mind reader has been discovered at Glasgow, Ky., or rather discovered himself accidentally, not long since. He is Flavius Taylor, the son of Dr. F. J. Taylor, a Glasgow physician. His age is 19 years, and some account of his doings has been sent to the *Courier-Journal* by Dr. P. C Sutphin, another of Glasgow's physicians, who is familiar with the young man's case, and has made a study of mind reading, as well as what is termed "muscle reading" by performers who claim to be guided by the thrills of the muscles of the subject. Dr. Sutphin gives some speculations at length on the alleged distinction between mind reading and muscle reading, and arrives at the conclusion that, though there may be trickery and imposture used by some people there is such a thing as mind reading, and no such thing as muscle reading. He quotes from Stuart Cumberland, an English mind reader, who claimed that he was guided by the muscles, and in a performance before the Khedive of Egypt, wrote a word thought of (the name of the Khedive's son, Abbas) on a piece of paper, in Arabic, a language of which he knew nothing, and this without a moment's hesitation. Cumberland said this was muscle reading, but Dr. Sutphin details a similar test with young Taylor, which, he claims, shows the mind must bear its part in such a test as well as the muscles. He is willing to say that some things may be done by muscle reading, but that others cannot. Dr. Sutphin, in his account of young Taylor's performance, says: "We may concede, however, all that Mr. Cumberland says of muscle reading; may agree that all his feats were performed by it; yet when it is attempted to include all mind reading in this, then it will be found that this cannot be done. There is much of mind reading, indeed, that could not be explained, nor, in fact, be accomplished, by muscle reading. This is fully proven by a lately developed mind reader here in the place in which I live—a young man, Flavius Taylor, 19 years of age, son of Dr. F. J. Taylor, a prominent physician and pension medical examiner. It is not improbable that in nearly every instance the gift of mind reading has been of accidental discovery on the part of the one possessing it, and thus it was accidentally made known to young Taylor. Several months ago an itinerant mind reader exhibited in this place and young Taylor attended his performance. Returning home, he playfully remarked to a young man who had accompanied him that he thought he would make a good mind reader, and that if the other would blindfold him and hide something he would find it for him. To have a little amusement, he was duly blindfolded and next told to find a book that had been hidden in an adjacent room. He now grasped the hand of the young man

who had hidden the book, but was utterly surprised to find that not only the book but also its place of concealment were impressed on his mind. He readily took the young man to the place where the book was and handed it to him. After this there were more or less frequent tests of his powers in finding things thus, while all hidden articles were always promptly located by him. Intermingled with these tests were others, such as willing him to do certain things. Say, for instance, that it was willed for him to take a particular flower of a number of flowers in a vase in the room, and to hand it to a certain young lady present; to remove the watch from the pocket of a certain gentleman and to put it into that of another certain gentleman; to go to a library and take out some particular volume in it, and turn to a certain page and paragraph or sentence in it, and so on of other requests of this sort. All these were readily and accurately done by him, down to the minutest particular of the wish. Mr. Cumberland, however, professes to have done things quite equal to this by muscle reading, being directed in them by the muscular tremors of the hand kept enclosed in his. In this way, he says, he only followed direction, and knew nothing really of the mind, and only did as tremors directed. He did, in other words, precisely what the hand he was holding would have done, directed by the individual. In this, of course, there was no mind reading, but a guidance only by muscle signalling. Suppose, however, it was required to take hold of the hand; and next tell any particular thought of the mind—not find anything or to do anything that the hand of the individual might do, but simply to take the hand and say, not act out, what the thought was—then this could only be gotten direct from the mind, and in no other way, as mere muscle reading in this case would simply be impossible. In this case it would be necessary to see thought itself, to tell what it was, which the thrill of the muscles would not admit of. And yet, young Taylor can do this. He has been mentally requested, for instance, to play a certain air on the organ, one of a number of others played by him, when catching hold of the hand to know what it was, he would go to the organ and play it, using both hands for the purpose. Had he been playing by direction only of the muscles of the hand, he could not have let go the hand and played with both hands. But he has done better even than this. Any figure, or any number of figures, being thought of, he has readily announced what it or they were, calling them out singly or in combination, if desired. For instance, suppose that the figures 5, 3 and 8 were separately thought of. Then these were promptly told out, one by one, and announced singly as thought of; or suppose, again, these were thought of as 538, then this number, or 538, would be told. Some time ago, knowing that he did not understand Latin, I improvised a short Latin sentence—'est mihi voluutas ut legis meam mentem'—and asked him to tell me what it was. This was made out slowly, but quite accurately, the words being spelled out letter by letter. It is proper to say, too, that these were called out at once, without going over the alphabet and getting at them in this way, one by one, on the order of table rapping.' Nothing was said, really, more than to call out the letters in their proper order. Without mentioning other feats of this young man the question next occurs: Upon what other ground can we explain this telling of figures and calling out Latin than upon the silent impress of mind upon mind? This is the explanation, in fact, that young Taylor gives of his 'mind reading,' as it is called; or that he only interprets every thing by impression. He knows nothing of muscle reading, feels nothing of the sort, sees nothing, hears nothing, is not aware even of any particular exaltation of the perception, but simply finds certain thoughts or wishes of another impressed on him. His great difficulty, he says, is to get a correct impression from some who either lack concentration of mind or allow the too frequent intrusion of other thoughts into it. For a good effect impressions must be forcible and sharp cut, and the mind must be kept steadily and as exclusively as possible on the subject. He thinks the hand acts only as a conductor of impression, and regards it indispensable for that purpose, as the current of impression is transmitted in this way, without which he could tell nothing. In conclusion, I may add that in his performance there is usually considerable disturbance of his physical being. His respiration often becomes slow and labored, pulse usually goes up from ten to twenty beats above normal to the minute, there is heavy sighing at times, and sometimes so much exhaustion as to necessitate temporary rest."

DOMESTIC DIETETICS.

SPECIALLY PREPARED, FROM PRACTICAL TESTS, FOR THE LADY READERS OF THE "AMERICAN ANALYST."

SEASONABLE FOOD.

August.

GAME AND POULTRY.—Pigeon, chicken, duck, woodcock.

MEAT.—Beef, lamb, mutton, ham, kidneys, liver, sausage, veal, venison.

FRUITS.—Cherries, raspberries, huckleberries, melons, gooseberries, blackberries, peaches, pears, tamarinds, bananas, pineapple, grapes, plums.

FISH.—Anchovy, bass, bluefish, blackfish, cod, eels, crabs, clams, flounder, halibut, herring, lobster, mackerel, mussels, porgie, prawn, salmon, turtle, trout, sturgeon, whiting, weak-fish, rockfish.

VEGETABLES. — Beans, beets, cucumbers, cabbage, carrots, cauliflower, corn, egg-plant, lettuce, onions, parsley, parsnips, potatoes, squash, shallots, spinach, turnips, radish, rhubarb, tomatoes.

PRACTICAL RECIPES.

CALF'S LIVER —Slice a liver very thin; fry out a few slices of bacon in a pan, or instead put a little olive oil and a little sweet lard in a pan; chop up some parsley, mushrooms, and a piece of a small fresh onion, and cover the bottom of the pan with them; put in a layer of liver, sprinkle with salt and pepper and another layer of the chopped vegetables; add again a layer of liver, then some more of the chopped vegetables; lay on this the slices of tried out bacon or some fresh slices, cover closely and cook. When done take out the liver, skim off the grease, and add flour and hot water to make a good gravy.

TOASTED CHEESE.—Weigh your eggs and beat them up in a saucepan; add to them a piece of butter the sixth of their weight and a third of their weight in grated Gruyere cheese; add a little salt and cayenne pepper. Put the saucepan over a bright fire, and stir constantly for a few moments until it is melted. Have ready some slices of thin toast on a hot platter; pour the fondue over this and serve at once.

SOFT SHELL CLAMS ESCALLOPED. — Purchase a dozen large soft clams in the shell and three dozen opened clams. Ask the dealer to open the first dozen, care being taken not to injure the shells, which are to be used in cooking the clams. Clean the shells well and put two soft clams on each half shell; add to each a dash of white pepper and half a teaspoon of minced celery. Cut a slice of fat bacon into the smallest dice, add four of these to each shell, strew over the top a thin layer of cracker dust; place a pat of table butter on top and bake in the oven until brown. They are delightful when properly prepared.

STUFFED POTATOES.—Put some large fine potatoes in boiling water and cook for a quarter of an hour; take them out, let them cool a little, cut off one end and carefully dig out the centre; have ready a forcemeat made of chicken, beef or veal, very highly seasoned. Fill up the potatoes with this. Put on the end you cut off and tie it down carefully; lay the potatoes in a pan and bake in a hot oven.

ARTICHOKE SOUP.—Take two pounds artichoke and peel them; put them to boil in two cupfuls water and two cupfuls milk, seasoning to taste with salt. Put in a saucepan half a pound of rice, a small fresh onion cut in two, and a turnip quartered; pour in four cupfuls of milk and cook. When the artichokes and the rice are both done put them together and mash them through a sieve. Make a cup of cream very hot. Put the puree again in the saucepan, season to taste, add the cream. Serve with the soup snippets of fried bread.

HAM CAKES.—Chop very fine two cupfuls of left-over cold ham, add to this half a cup of fine dry bread crumbs and two well-beaten eggs; season with pepper and a few drops of onion juice; form into little cakes and fry in hot fat for breakfast.

RICE CUSTARD.—Make a custard with a pint of milk, two eggs, sugar, grated nutmeg and vanilla. Add to it, before pouring into the cups, half a pint of boiled rice; mix and keep surrounded with ice until wanted.

A PIE CHAMPION.

THE POLITICAL POSSIBILITIES OF PUMPKIN PIE.

The world, says the *Sun*, has a new Mrs. Ewing—not a writer of delightful story books for children and about children, as was the late Juliana Horatia Ewing, but a woman who knows how to cook and how to teach others to cook. She has been telling what she knows about cooking and illustrating it by practical examples before large audiences at the summer school at Chautauqua; and she has actually ventured to say a good word on behalf of pie! When a qualified cook declares that the most delicate desert can be prepared at a cost of only a cent and a half a plate (notwithstanding the McKinley tariff and the lack of reciprocity with Canada), and then proceeds to prove it by feeding her hearers with delicious dainties, what she says about pie is not to be sniffed at, especially when her words are of political as well as economical import; "The trouble nowadays is that we pass over the soup at dinner because it is slop. We cannot eat the meat and vegetables because they are imperfectly cooked, and we devour pastry only because of the flavor, hence a nation of dispeptics. Cook knowledge as well as book knowledge is needed in this broad land of ours, and the offer of a good rich piece of pumpkin pie to every individual in attendance would draw a bigger crowd together than any political or religious meeting ever held, so much do people yearn for good food." At last the sentiments of the American pie eater have found an able and fearless advocate and expounder. In no one attribute is the unity of the New England stock, which has overspread the land from Maine to California, more evident than in the fondness of its individual representatives for pie. Before the war, barbecues, at which whole oxen were roasted, were the great political feasts in the Middle and Southern States. For these, as we gather from the words which we have quoted, Mrs. Ewing would substitute pie suppers. To campaign committees she says, in effect: "Don't waste your money on powder, or fireworks, or banners, or bands. Spend it for pie! Where the good rich pumpkin pie is, there will the qualified electors be also; and having once attracted them by pie and pleased them, they will remain to hear politics."

GAS IN LONDON.—The use of gas is extending enormously for domestic purposes in heating and cooking, as well as lighting. Some 3,000 gas engines are said to be in use in London, and the number of gas stoves now in daily use in the metropolis is stated to be no less than 70,000.

IDEAL TEA.

HOW TEA IS CONVERTED INTO OLD MAIDS' BOOTS.

The following advice concerning the somewhat familiar institution of tea-drinking, emanates from the versatile pen of Dr. Edward Bedloe, of Philadelphia, the present United States Consul at Amoy, China. When I left Philadelphia, I thought I was a fair judge of tea. I had imbibed both it and the knowledge of it in large quantities from George C. Boldt, John Chamberlin and Delmonico. Now, after having visited Ceylon, Formosa and the Amoy district, I find that I knew nothing, and the three worthy gentlemen named knew even less. We Americans don't know the first principles of making tea. The delicate leaf should never touch metal. It should be kept in paper, wood, glass or porcelain. To make it, put a small quantity in a porcelain cup, fill the latter with boiling water, cover it with a porcelain saucer and let it stand three minutes. Then if you desire to be an epicure, drink only the upper layer of the golden liquid, throw the rest away, rinse the cup and begin drawing *de novo*. Don't use sugar any more than you would sweeten Chambertin or pour molasses into Mumms' Extra Dry. Don't use milk. It ruins the flavor of the tea and injures the stomach. The cloudiness produced by adding milk to tea arises from the action of the tannin upon the casein, and is, chemically speaking, pure leather. An old maid who drinks a dozen cups of this mixture a day swallows a hundred pair of boots and a section of extra long leather hose during her lonely life of fifty years. Above all things don't boil tea. The heat drives off the perfume, spoils the flavor and extracts the tannin, the astringent principle. If the boiling be done in a tin or iron pot the tannin attacks the metal and makes the liquid black. This fluid is simply diluted ink. Never let the tea stand except in a tightly-closed porcelain pot. Standing changes it from a delicious wholesome beverage into an ill-tasting and bitter liquor. Rather make it in small quantities and make it often. Methinks I hear many good housewives say, "It needs no ghost to tell us this," and yet there are thousands who do need advice on this simple subject. In summer, when you want to cool off quickly, sip the tea boiling hot, with a slice of previously peeled lemon or nicer still of orange, without the rind, floating in it. In winter, especially when you have a cold and require a sudorific, add a wineglassful of arrack to it and drink it down as hot as you can stand it. It will bring out a profuse and healthy pespiration when punch or hot Scotch fail to thaw you out. Beware of green tea! It is an abomination and a fraud. A Chinese Coolie wouldn't give it to his pig. He will give that patient porker dead rats, old boots and other offal, and such unconsidered trifles, but he draws the line at green tea. In the first place it is simply the unripe leaf and bears the same relation to the real article that the "little peach of Emerald hue" does to Delaware's delicious fruit in its richest ripeness. It has the same effect upon the stomach and abdominal nerves as in the case of poor "Johnny Jones and his sister Sue." The green tea of commerce derives its rare color from being cured, or rather killed, on dirty copper pans, from being mixed with weeds and shrubs, from being stained with indigo and chrome yellow, from being colored with verdigris, grass-juice or chlorophyl. Every green dye known to commerce has been used to produce the much admired but death-dealing color, excepting it may be Paris green. As soon as the use of that poisonous substance will give a profit of a cent a pound, you can wager that it will be liberally used by the mercenary Mongolian merchant and the much more mercenary cultured European tea-trader. I'll venture the statement that there is no fine tea in the United States. What goes to our country is the cheap stuff used here by the coolies and jail inmates. When an American housekeeper pays $1 per pound for her Oolong or English breakfast, she is buying what is sold here for twenty-fives cents. No really good tea is sold here for less than $1 per pound by the wholesale. If laid down in the market at home it could not be sold for less than $1.75. This $1 tea is the usual article for clerks, poor tradesmen and mechanics. For the well-to-do, the official class and the nobility, are finer pickings that run from $1 to $50 per pound. The only Europeans who purchase these high-priced leaves are the Russians and a few connoisseurs in France, Germany, Austria, Spain and Turkey. The bold Briton permits patriotism and his purse to guide his palate, and uses the vicious vitriolic horrors of Ceylon and India. Good Uncle Sam patronizes a Cheap John who gives away to each purchaser a $2 cup and saucer with every 25 cent pound of tea. The tea plant is as sensitive and delicate as a West Walnut Street belle. It flourishes best on a mountain side, where it is neither very warm nor cool, where the soil is dry, but the rains and dews are frequent, where the force of the wind is broken by adjacent woods or hills, where there is a maximum of sunlight and, according to Celestials, of moonlight, and where the surrounding ground is kept free from weeds or other vegetable growths. There are farms in Formosa, Fo-Kien and other tea districts where these conditions exist unchangingly, whose tea crop is as famous and as distinctly known in the Eastern world as the various chateaux of France are to the wine experts of Europe. Just as the millionaires of Europe control certain vineyards, so do the millionaires of the Flowery Kingdom control tea plantations whose annual output is worth a king's ransom. Another point of the many we have to learn from the Chinese, is the proper mode of packing the leaf. That which goes to America is dumped as soon as it is "fired," burning hot into a lead-lined box, the lead is soldered and the air-tight coffin is sent around the globe in the hot hold of a steamer. The tea sweats, and undergoes many changes which alters its flavor altogether and vitiates its quality. The Mongolian packs the poorest kind in strong paper packages and these in turn in mortuary lead; the better kind in soft tin paper-covered boxes; still better ones in silver-foil inside of one pound cases made of split sun-dried bamboo, and the best in porcelain jars and vases. He packs in eighths and quarters of a pound, so that if a few leaves are improperly treated or not cured, they will not contaminate much surrounding tea. The Russians compress the tea into bricks, or cover it with silver-foil and many paper wrappings, or else put it in glazed jars. The principle is the same—the subdivision of the tea, and the prevention of risks attending larger packages or in bigger bulk, such as heating, sweating and moulding. This principle we have yet to learn and apply. But ah, the exquisite pleasure to be found in a cup of truly fine tea. The color is a delicate gold; each leaf unfolds into a perfect olive oval; its fragrance fills the banqueting hall, delicate yet penetrating, dainty but distinguishable above all other perfumes, and the flavor! The famous Clover Club Punch pales into dim distance in comparison to this "cup that cheers." Words cannot describe the delight of a brew of fresh Formosa tea. It fills the system and makes every nerve thrill with joy. It lingers on the palate for hours. And "the next day," think of it, O votaries of Bacchus! the brain is clear, the body all alert and the soul ready for the battle of life.

ALCHEMY.

THE OLDEN SEARCH FOR THE PHILOSOPHER'S STONE.

A case recently before the courts induces me to offer a few notes on this subject. Alchemy is said to have been commenced by Hermes Trismegistus, an ancient Egyptian king, and from its earliest ages the discoverer of the philosopher's stone, which was to transmute all baser metals into gold, was one of its chief objects—if, indeed, this were not a cause of its foundation. Those who advocate the great antiquity of chemistry conceive that the alchemical secret is metaphorically concealed in the fable of the Golden Fleece of the Argonauts, rejecting the more probable solution of the story of Strabo, who says that the Iberians, near neighbors of the Colchians, used to receive the gold brought down from the high lands by the torrents into sieves and sheep skins, and that from thence arose the fable of the Golden Fleece. Dionysius of Mytelene offers a different explanation, and supposes it to allude to a book written on skins, and containing an account of the process of making gold according to the art of alchemy. Either of these explanations proves the great value that was set upon gold even in those remote times. The Arabians, it is supposed, introduced gold, silver, etc., into their materia medica, and surprising virtues were attributed to them. Among a people so disposed to magnificence, and, from the very spirit of their religion, credulous and romantic, it is scarcely a matter of surprise that their first researches into the nature of bodies should have raised a hope, and excited a belief, that the baser metals might be converted into gold. They conceived that gold was the metallic element in a state of perfect purity, and that all the other metals differed from it in proportion only to the extent of their individual contamination; hence the origin of the epithet base, as applied to such metals. The alchemists, however, were not satisfied with the idea of changing the base metals into gold; they expected by the same means to produce a universal remedy, the elixir of life, calculated to prolong indefinitely the span of human existence. It is difficult to imagine what connection could exist in their ideas between the philosopher's stone, which was to transmute metals, and a remedy which could arrest the progress of human infirmity. Upon searching into the writings of those times, it clearly appears that this conceit originated with the alchemists from the application of false analogies, and that the error was subsequently diffused and exaggerated by a misconstruction of alchemical metaphors. An example of reasoning by false analogy is presented by Paracelsus in his work "De Vita Longa," wherein, speaking of antimony, he exclaims: "*Sicut antimonium finit aurum, sit, eadem ratione et forma, corpus humanum purum reddit.*" The processes of alchemy were always veiled in the most enigmatic and obscure language. The earliest alchemist whose name has reached posterity is Geber, an Arabian prince of the seventh century, whose language was so proverbially obscure that Dr. Johnson supposes the word "gibberish" to be derived from his name. Sometimes the processes of alchemy were expressed by a figurative and metaphorical style of description. Thus Geber exclaims, "Bring me the six lepers that I may cleanse them," by which he implied the conversion of silver, mercury, copper, iron, tin and lead, the only metals then known, into gold. From the works of later alchemists, it also appears that they constantly represented gold as a sound, healthy and durable man, the imperfect metals as diseased men, and the means of processes by which the latter were to be transmuted into the former they designated by the name of medicines; hence those who were anxious to dive into the secrets of these magicians (or adepts) without possessing the key to their language, supposed that these descriptions were to be understood literally, and that the imperfect metals might be changed into gold, and the bodies of sick persons into healthy ones, by one and the same chemical preparation. This hieroglyphical style of writing, adopted by the earlier alchemists, was, in a great degree, supported by the prevailing idea that the elements were under the dominion of spiritual beings, who might be subjected to human power, and Sir H. Davy has observed that the notions of fairies and of genii, depicted with so much vividness in the "Thousand and One Nights," seem to have been connected with the pursuit of the science of transmutation and the production of the elixir of life. Pliny says

that the Emperor Caligula was the first who prepared natural arsenic in order to make gold of it, but abandoned the attempt because the charge exceeded the profit. Some say that the Egyptians knew the secret. In 1405 the "craft of multiplying gold and silver" was made a felony, which would seem to indicate that roguery was increasing in that direction, but the act was repealed in 1689. In 1476 a license to practice alchemy was granted to one Richard Carter. Sir W. Raleigh, during his imprisonment in the Tower, employed himself largely in chemical experiments, and believed that he had discovered an elixir of life. In 1782 a Dr. Price, of Guildford, published an account of his experiments, in which he pretended to success. He brought his specimens of gold to the King, affirming that they were made by means of a red and white powder. Being a Fellow of the Royal Society he was required, upon pain of expulsion, to repeat his experiments before Messrs. Kirwan and Woulfe, but, after much equivocation and delay, he committed suicide. In 1860 a Hungarian refugee, named Papaffy, represented that he had a system by which he could transform metals into sterling silver. Strange to say, he induced numbers of men of position to advance capital for his operations, when, having raised over £10,000, he quietly decamped. In conclusion, the following process, as recommended by Raymond Sully (born 1235), may be mentioned: "To make the elixir of the sages, or the philosopher's stone, take the mercury of philosophers (lead), calcine it until it is transformed into a green lion (massicot); after it has undergone this change calcine it again until it has become a red lion (minimum). Digest this red lion in a sand bath with acid spirit of grapes (vinegar), evaporate this product, and the mercury will be converted into a kind of gum acetate of lead); put this into a luted cucurbit and distil it with heat. You will obtain an insipid phlegm, then spirit and red drops. Cymmerian shades will cover the cucurbit with their sombre veil, and you will find in the interior a true dragon, for he eats his tail (*i. e.*, the distilled liquor dissolves the residuum). Take the black dragon, break him on the stone and touch him with red charcoal; he will burn, and assuming a glorious yellow color, he will reproduce the green lion. Make him swallow his tail, and distil this product again. Lastly, rectify carefully, and you will see appear burning water and human blood." This substance, called by the alchemists human blood, is a reddish-brown oil, which is formed during the distillation of the acetic acid in the above process. It has the property of precipitating gold from solution containing that metal, which probably gave rise to an idea that it possessed the virtues which were so eagerly sought after. I am indebted for most of the information in this article to "Paris Pharmacologia," "Haydn's Dictionary of Dates," and Bell and Redwood's "Progress of Pharmacy."—*Brit. and Col. Drug.*

Exhaustion

Horsford's Acid Phosphate.

The phosphates of the system are consumed with every effort, and exhaustion usually indicates a lack of supply. The Acid Phosphate supplies the phosphates, thereby relieving exhaustion, and increasing the capacity for labor. Pleasant to the taste.

Dr. A. N. KROUT, Van Wert, O., says:

"Decidedly beneficial in nervous exhaustion."

Dr. S. T. NEWMAN, St. Louis, Mo., says:

"A remedy of great service in many forms of exhaustion."

DESCRIPTIVE PAMPHLET FREE.

RUMFORD CHEMICAL WORKS,

PROVIDENCE, R. I.

BEWARE OF SUBSTITUTES AND IMITATIONS.

CAUTION:—Be sure the word "Horsford's" is *printed* on the label. All others are spurious. Never sold in bulk.

BUSINESS NOTES.

HORSFORD'S ACID PHOSPHATE

Relieves the feeling of lassitude so common in midsummer, and imparts vitality. Dr. L. C. S. Turner, Colfax, Ia., says: "I am very much pleased with it in mental depression from gastric troubles."

WARNER'S PILLS.

We beg to call the attention of our subscribers to Messrs. Warner's advertisement. Their pills are thoroughly reliable, and being carefully sugar-coated, are entirely tasteless. The use of sugar as a coating for pills has been objected to. It has been stated by some that in sugar-coated pills the drugs become dry and hard, and soon lose their efficiency. This we can state for a positive fact not to be the case, having lately used and examined some of Warner's pills which had been kept in stock for over four years, and in which, on section, the mass was found to be quite soft. From our own experience, we have no hesitation in recommending others to use these preparations, as they are sure to be reliable and to give satisfaction.—*Canada Medical and Surgical Journal.*

MUSKY MOSQUE.—When the mosque of St. Sophia, in Constantinople, was built, more than one thousand years ago, the stone and brick were laid in mortar mixed with a solution of musk, and the building, it is said, has been infected with the odor ever since. Probably age has imparted a musty odor, from which the musk story was fabricated.

CHEAP DISINFECTANT.—A disinfectant that costs very little and is perfectly odorless, is made by dissolving a heaped teaspoonful of nitrate of lead in a quart of boiling water, stirring it with a stick and then adding it to a pail of cold water. This is odorless and will not stain; it costs about 3 cents, and if it is thrown once a week down the bath-tub, closet and stationary wash-bowl, it will be money well spent.

ONION GLUE.—Paper may be securely gummed to metal by the aid of onion juice. The dials of cheap clocks used to be printed on paper and then glued to a zinc foundation, but after a short time the paper came off the metal. Now the zinc is dipped into a strong solution of washing soda, and afterwards is washed over with onion juice. The paper is then pasted on, and it is almost impossible to separate it from the metal.

OIL FOR FUEL.—Coal is scarce and high in the Argentine Republic, and many of the locomotives of the Argentine Great Western railroad are being fitted for the use of petroleum as fuel, and it will probably supercede all other fuel on that road. The oil used is a heavy petroleum found at Mendoza, near the line of the road, which answers the purpose of fuel fairly well, although it has been found impossible to refine it so as to make a good lamp oil. The economy is very considerable as the railroad company can procure this oil at present at a cost of $12 paper per ton—equivalent to about $3 gold—while English coal, which has been used on parts of the line, costs $20 gold, per ton.

ORIGINAL. No. 30.

Hominy Gems.

BY MRS. D. A. LINCOLN,
Author Boston Cook Book.

Mix 2 table-sp. fine, uncooked hominy, ½ tea sp. salt, 1 table-sp. butter, and ¼ cup boiling water. Place this over the tea kettle until the hominy absorbs all the water. Pour 1 cup boiling milk on 1 scant cup fine yellow corn meal; add 2 table-sp. sugar and the hominy. Let it cool slightly, then add the yolks of 2 eggs beaten to a light froth, then the whites beaten stiff. Stir in 1 level tea sp. Cleveland's baking powder and bake at once in hot buttered gem pans, about 20 minutes. A scant cup of cold boiled hominy may be used instead of the fresh hominy. It should be sifted through a squash strainer, to free it from lumps.—(Copyright, 1891, by Cleveland Baking Powder Co.)

Use only Cleveland's baking powder, the proportions are made for that.

"Cleveland's Baking Powder; the best in quality, highest in leavening power and perfectly wholesome." A. F. Underwood, U. S. Government Chemist, 1891.

PURE PEPSIN

In Powder and Scale.

MANUFACTURED BY

ARMOUR & COMPANY,

Chicago.

Guaranteed free from adulteration or make-weights; of excellent physical properties and high digestive power.

Under similar conditions, **ARMOUR'S PEPSIN** will exhibit greater activity than any other pepsin now before the profession.

The Manufacturers will be pleased to supply members of the Medical Profession with samples of their Pepsin, and with full details regarding digestive strength, if desired.

SEE PAGE 381 FOR VALUABLE OFFER.

WATCHES.

EVERY one wants a watch, and naturally a good watch that keeps accurate time, presents a handsome appearance, and is inexpensive. If such a watch can be found of American manufacture, it is an additional appeal to our patriotism. Just such a watch as this ideal THE ANALYST PUBLISHING COMPANY is enabled to offer as a Premium to its readers. Having some large advertising contracts we have been enabled to procure the movements of the manufacture of the best known American watch factories, namely, the Waltham, Elgin, Hampden and Illinois Watch Companies. These movements are adapted for both ladies' and gentlemen's watches, and are warranted by the makers. These movements have seven jewels, patent lever movement, chronometer balance, patent safety pinion, sunk hard-enameled dial, straight line visible palette, stem winders, hand set; in fact, contain all the latest improvements and can be readily cleaned or repaired by any ordinary good watchmaker. They can be regulated to run as close as any movement.

It is needless to say that to case these movements in solid gold cases would make them too expensive, yet they are cased in what are known as gold filled or stiffened "Ladd" cases, and are warranted to be 14 karat gold, made from two sheets of 14 karat gold overlaying fine composition metal, with regular jointed caps, covers and bezels, and to wear at least five years. They are not plated, nor rolled gold, but actual 14 karat gold cases, thin of course, but stiffened and strengthened by being filled with this fine composition metal. They are finished in the same manner, engine turned and engraved as solid gold watches, and wear and look just the same. No one but an expert can tell them from a solid gold watch. These watches are made both open face and hunting case style, in gentlemen's or ladies' sizes. For gentlemen we recommend plain engine-turned cases; for ladies, a handsomely engraved case.

How to Obtain One of these Watches.

These watches are not to be purchased from us at any price. Send us a club of 25 subscribers to the AMERICAN ANALYST, and $25, the regular subscription price, and one of these watches (your choice of style and size) will be immediately forwarded, post-paid and registered, to your address. You need not wait until you have your 25 subscribers all together, but forward them as you get them and they will be credited to you, and when the number is complete the watch will be sent. A subscription for two or three years will be counted as two or three subscribers.

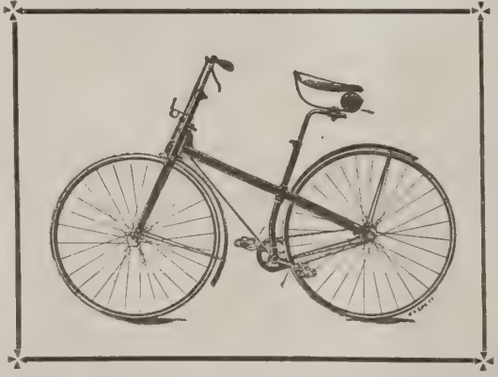
As these watches are retailed by jewelers at not less than $25, it will be seen that we are offering a real premium with the sole object of increasing our circulation, and that by taking advantage of our offer any one can obtain a good, reliable and handsome watch without cost. As the number of these watches at this price is limited, it is advisable to take steps at once to procure a bargain.

THE ANALYST PUBLISHING CO., 19 PARK PLACE, NEW YORK.

BICYCLES

GIVEN AWAY TO BOYS AND GIRLS!

AN OPPORTUNITY OPEN TO ALL.



The Analyst Publishing Company being desirous of largely increasing their subscription list, will furnish every one with a beautiful Safety Bicycle, ABSOLUTELY FREE, in return for a few hours' canvassing.

To every boy and girl who secures 75 subscribers for the American Analyst at $75, we will give a splendid

$40.00

NONPAREIL

SAFETY BICYCLE.

These bicycles are adapted in size to boys, but are strong enough to carry a man. A boy's bicycle should be a strong one. They are manufactured by the OVERMAN WHEEL CO., the makers of the celebrated VICTOR Bicycle, and have the full guarantee of the makers.

The following is a brief description of the NONPAREIL SAFETY; 26-inch wheels; ball bearing all around, including pedals; solid crescent rims; double tangent spokes; three-fourths inch tires; cranks, three throw, $4\frac{1}{4}$ to $5\frac{3}{4}$ inches; guards to both wheels; tool-bag, oiler and wrench. Finished in bright enamel, all exposed metal heavy nickel-plate on copper.

In selecting these machines as a premium, we have disregarded cheapness and selected a Bicycle which is serviceable, and the makers of which have an established reputation for building the best Bicycle that money, machinery and brains can produce. We are actually furnishing the Bicycles and Papers at less than cost, but hope by stimulating active and successful canvassing, and thus enlarging our subscription lists, to make an eventual profit. We positively guarantee these bicycles to be just as here represented. They will be shipped by express f. o. b. in New York.

Subscription orders must be made out plainly and legibly, and sent as fast as secured, addressed to

THE ANALYST PUBLISHING CO., 19 Park Place, New York.

ONE YEAR FREE.

If you will send us the addresses of Twenty-five Ladies in your neighborhood to whom we can send sample copies of the **AMERICAN ANALYST,** we will send this paper to you free for One Year; or, for Fifteen names, Six Months; or, for Ten names, Three Months. We do this because our past experience assures us that any lady who once becomes acquainted with the value of the **AMERICAN ANALYST,** continues to subscribe for it. We also offer valuable premiums for raising clubs.

TABASCO PEPPER SAUCE,

OR LIQUID PEPPER.

Is simply the Pulp of the Ripe Pepper Extracted by Pressure.

The seed of this Pepper was obtained from Central America, and by careful cultivation in Louisiana for many years has been so improved in strength, flavor and aroma, as to have become a new variety of Red Pepper, superior to all others. The pulp is so handled as to retain all the flavor, strength, aroma and color of the ripe fruit, and to keep unimpaired in any climate. It excites the appetite, promotes digestion, and is pronounced by connoisseurs to be the finest condiment in the world. For medicinal purposes it recommends itself by its purity, strength and diffusible form.

Manufactured by E. McILHENNY'S SON,

NEW IBERIA, LA.

For Sale by all Wholesale Grocers.

NATRONA BI-CARBONATE OF SODA.

ABSOLUTELY PURE.)

The nature of the raw material from which NATRONA BI-CARBONATE OF SODA is made—viz., kryolith, a mineral containing *pure sodium*—insures a purity and uniformity of product which cannot be obtained from any other known material. In making BI-CARB. SODA from any other raw material, the use of sulphuric acid is a necessity, but none is used in any part of the process of making NATRONA BI-CARB.; hence its entire freedom from the slightest trace of arsenic, which is always present in ordinary soda. Its absolute purity and entire freedom from all traces of *sulphate of soda*, common salt and other impurities, render NATRONA BI-CARB. NEARLY TASTELESS, and being bolted through the finest bolting-cloth, insures the finest stage of division.

To these indisputable facts the attention of CONSUMERS of soda is specially called. They are IMPORTANT, and should influence both those who use and those who sell soda, to buy and sell NONE BUT THE BEST.

The NATRONA BI-CARB. Soda is kept in stock by almost every wholesale druggist and grocer throughout the United States, of whom it may be ordered.

Natrona Bi-Carb. Soda is unequaled by any other brand of English or American Manufacture.

INSTRUCTIONS TO SUBSCRIBERS.

The **Names of all Subscribers** are registered as soon as received, and paper is always promptly forwarded.

Postage.—The postage to all parts of the United States and Canada is paid by the publisher.

Remittances of small sums may be made with comparative safety in ordinary letters. Sums of one dollar or more must be sent by registered letter or P. O. money order, otherwise we cannot be responsible for same. Silver must not be sent in a letter.

Postage Stamps will be received for the fractional part of a dollar, and in any amount when it is impossible for patrons to procure bills, but you must send one or two-cent stamps only.

SUBSCRIPTIONS.—The AMERICAN ANALYST will be sent one year to any subscriber for ONE DOLLAR. New subscriptions can begin at any time.

We Stop the Paper at the expiration of the time paid for unless a renewal of subscription is received. Those whose subscriptions have expired must not expect to continue to receive the paper unless they send the money to pay for it.

Change of Address.—Subscribers wishing their addresses changed must invariably give their former as well as new address.

Missing Numbers.—It occasionally happens that numbers of our paper sent to subscribers are lost or stolen in the mails. In case you do not receive any number when due, write us a postal card and we will cheerfully forward a duplicate of the missing number.

Most Important of All.—In every letter that you write us, never fail to give your full address, plainly written—name, post-office, County and State.

MIDSUMMER REFLECTIONS.

It is now nearly seven years since the AMERICAN ANALYST began its mission as an advocate of pure food and an opponent of sham products. The history of its labors in that field, even if confined to a reviewal of the success it has achieved in exposing and defeating unscrupulous schemes involving risk to the health and depletion to the purse of the public, would require greater space to rehearse than is available within the limits of this page. The shades of defunct swindles in the shape of pretended nerve foods, possessing the potency of root beer; of alleged opium cures, better calculated to stimulate than to destroy the craving for that soul and body debasing drug; of baking powders stuffed with poison, and of a host of other exposed sophistications in the various departments of food, drink and pharmacy, are still flitting about the graveyard of illicit cupidity, awaiting absorption into the limbo of fraudulent failure to which the efforts of the AMERICAN ANALYST have consigned them. Our uncompromising denunciation of charlatans, adulterators and handlers of poisonous food, has operated to the advantage of the public generally and of the manufacturers of genuine goods specifically, and the latter have not been slow nor niggard in their recognition of our services. As we have heretofore had occasion to explain, in relation to the purposes of this journal, humbugs seeking to enrich themselves through the sale of high-sounding specifics for various human ailments, are subjected to the crucial test of thorough chemical analysis of their goods, and where the latter, as too frequently occurs, prove to be frauds, the facts are placed before our readers in order to save the public from further unconscious imposition. The veil of chemical mystery in which tricksters of this kind ostentatiously envelope their processes of manufacture, protects them from the criminal laws to which other confidence operators are held amenable, and the only method as yet for counteracting their nefarious schemes is through public exposure by the newspaper press. The bunco steerer, the counterfeit money vender, and the whole class of rogues who prey upon the lawless greed of mankind, are far less culpable, from a moral standpoint, than their more expert brethren in rascality, who fatten themselves by the sale of worthless concoctions which they falsely represent as competent to relieve the physical sufferings of their fellow creatures. The AMERICAN ANALYST, in addition to the warfare it wages against that species of malefactor, co-operates regularly with the Boards of Health of this and other cities in efforts to secure sanitary and food reforms through organized efforts, and it is conceded to be the only popular medium through which those bodies can bring their purposes and action intelligently before the general public. Reaching as it does all classes—manufacturers, merchants, physicians, chemists, and private families—all over the land, its influence is exerted over a vast radius, producing results as visibly marked as they are widespreading. The abuses it is combating are too numerous and powerful to be speedily suppressed. The effrontery of fraud combined with the arrogance of capital constitute a resisting force not readily overcome, though the ultimate issue is inevitable. The scope of this journal, however, is not limited to the missionary work above described. Its varied contents cover almost the entire field of scientific as well as social progress, and each yearly volume constitutes a compendium of current facts in nearly every department of knowledge such as can nowhere else be obtained in such comprehensive shape and so cheaply. In this relation we take occasion to publish here a few extracts from a large number of similar compliments that we have received from strangers as well as from our regular patrons. A New Haven editor writes: "As a newspaper man, and one with a strong, active instinct for good miscellany matter, I want to congratulate you on your publication. The ANALYST is certainly a unique and valuable periodical, and I feel sure that if you press its sale you will gather in thousands who are waiting only to see it before subscribing." A London editor writes us: "I have just seen your excellent paper for the first time, and I am quite delighted with it. I wish you would exchange it for my magazine." A New York journalist, one of the most famous in the profession in America, bore down on us with the following unexpected praise: "I cannot refrain from congratulating you on the ANALYST. Its brainy suggestions make it one of the most welcome of my exchanges." A well known scientist says, in the course of a letter on other subjects: "Part of my leisure this summer has been devoted to cutting up my files of scientific papers. It may please you to know that I was astonished to find how perfectly you have kept the ANALYST abreast of scientific thought. It is indeed a valuable paper, and I congratulate you on your success in making it so worthy an addition to technical literature." These extracts will suffice to show the estimation in which the AMERICAN ANALYST is held by experts familiar with its purposes and methods. It is essentially a paper for the family, and with the low subscription price of only one dollar, it ought to find regular and welcome lodgment in every household in the United States.

THE SUBSTITUTE IMPOSITION.

The attention of the National Editorial Association during its recent convention at St. Paul, Minn., was called to a species of fraud which, though petty in detail is very extensive in the aggregate, known as the substitute swindle. The operation of the business was thus explained: There are many pharmaceutical preparations of a standard character which have attained to a high sale and widespread reputation by their legitimate merits, and the liberal advertising of their proprietors. Certain unprincipled druggists and small dealers have taken advantage of these circumstances to counterfeit these goods by imitating them just closely enough to keep themselves out of the clutches of the law. In Detroit, and in other cities, there are houses whose entire business consists in manufacturing imitations of these articles or "substitutes," which are made so as to closely resemble the originals in materials used, in the name, and in the general appearance of the boxes, bottles, or wrappers. As an inducement to these small dealers, and the better to enable them to carry out the swindle, their names are frequently printed on the packages by the manufacturers, and the false caption "our own make" is often added. It is easy to see how the swindle is worked. A customer inquires, for instance, for Blank's Emulsion; the dealer replies that he has it—which probably is untrue—but he recommends the customer to buy a preparation put up by himself, which he claims to be equally as good, and which, he says, he can recommend because, he pretends, he has

"compounded it himself" and it is his "own make," and besides, while Blank's Emulsion may be 50 cents a bottle, he can sell his own preparation at 25 cents. Nine times out of ten the customer, relying on the statement of the druggist, will be induced by motives of economy to take the substitute, which, of course, is worthless and may be dangerous. The dealer is enabled to do this because he buys very cheaply from the manufacturer, and thus the two get the benefit of the advertising of the genuine material and divide large profits. Thus an unsuspecting public is swindled. It is needless to say that the dealer who will descend to this contemptible business merely because he can make a larger profit upon the substitute than he can upon the genuine article, is a common swindler, and none the less because the trick is devised so cunningly as to save him from prosecution and deserved punishment. It is a fraud upon manufacturers who are making a legitimate article, and who have spent thousands of dollars to bring it before the public, and a fraud upon customers who are tricked into buying a bogus article which is worthless, if not something worse. It is time that this contemptible business was stopped, and it can be if the press of the country will ventilate and expose it, and if the public will refuse to patronize druggists who palm off these nostrums upon it. Customers should demand the article they have every reason to believe is the best, and if the dealer begins the old story recommending a preparation he has made himself, which he knows to be pure because he made it, which has his name on the wrapper, etc., it should be sufficient cause to refuse it promptly and go elsewhere for their goods. It is the lowest and meanest form of common thievery, and if the public will join hands with the press it can be broken up. It is certainly for the interests of the former to do so, as it is the principal sufferer.

AN ICE CREAM FACTORY.

DESCRIPTION OF AN ICE CREAM CAVERN IN THE METROPOLIS.

The following interesting account of the manufacture of ice cream in one of the large wholesale establishments of New York is from the N. Y. *Sun* of August 2. The scene is laid underground in a locality in the "down-town" section of the city. Descending a flight of steps the main floor was reached by the reporter and his guides, whence corridors branched forth in all directions, and each corridor was well filled with busy men who toiled in silence. So intent were they upon their work that they scarcely noticed the stranger's advent, although each one smiled upon and nodded to the guides. Strewn about in great but orderly profusion were countless boxes, vats, tanks, casks, barrels, and numerous other receptacles, each one either surrounded by or filled with ice. Then there was an imposing array of stout-looking ironclad cans containing pure cream, cooled almost to the point of freezing. And it was ready to be frozen, too. The cavern was an ice cream factory—the largest of its kind in New York city, and probably in these United States. It occupies the entire cellar and sub-cellar of a big down-down building and is always in operation, although it is only in full blast during the summer season. It was in full blast on this occasion. In one section of the large room was a group of men. They were preparing the rich, pure, raw cream for the freezers. After having been properly flavored with expressed fruit juices the huge cans, not quite filled, yet containing several gallons of cream, were conveyed to the whipping wheels. There blades or whippers were inserted in the cans, covers were tightly clamped on, and steam power brought to bear upon the machinery. This started with an ear-rasping squeak and a subdued roar, which was quickly succeeded by a crushing, grinding noise as the cans were whirled about in their beds of ice and the whippers did their work. For ten minutes this continued, and then the cans were removed to make room for others. Thus the process continues throughout every day of the rush season. Nobody in any of the departments has a chance to be idle. Everybody, in fact, has to hustle himself to keep up with the others. From the mixers and the whippers the cream, which by this time has considerable consistency, is passed to the hands of expert brickmakers, who work at a long, wide table. How their hands fly as they load the moulds! How their white-capped heads bob about and their spotless aprons flutter as they bend all their energies to their work! Deftly, layer upon layer of cream is laid in the zinc pouches. One man quickly but neatly dashes in a quantity of water-ice and some vanilla cream. The receptacle is passed to another workman, and he, with equal dexterity, adds strawberry and chocolate creams in sections, claps on the cover tightly, and buries it in salt and ice in a corpulent-looking freezer at his elbow. There the temperature is eight degrees below zero, and there that little brick of cream reposes until it is frozen solid. Next the freezers containing the bricks are rolled around to the opposite side of the table. As fast as one man is able to remove the zinc moulds another takes them from his hands. At his side is a cask of hot water. Into this he plunges the brick and gives it a terrible scalding, although of only a moment's duration. It is, however, sufficient to cause the brick to relax its hold on its coffin, and when the expert sharply raps the metal upon the table the brick, in beautifully variegated colors, drops upon the table a glistening, oblong square of sweets. Instantly the expert seizes it, and with flashing speed, but unerring accuracy, places it on the bed of a queer little machine, which is called a slicer. One downward movement of a lever and six set knives cut the brick into six equal portions. These toothsome bits are handed to other men, who quickly wrap them in white paper overcoats, fit them into pasteboard boxes, and they are then passed to still other men, who pack them away in great storage tanks, where the weather is like a Manitoba midwinter; then they are ready for the market. Branching off from a corridor formed by a series of white-painted pillars is a different set of men. They are busy, too, but, while their work is similar to that of the others, still it is more complex and difficult. These men make and freeze the French and other finer and more expensive varieties of creams, glaces and ices. They also mould the works of art in ice cream which so often adorn the banquet tables on occasions of public or private consequence. At short notice they produced a life-like representation of the Father of his Country. His features, which, by the way, were of vanilla cream, were easily recognized, but not his chocolate wig. His regimentals might have passed muster at a long-distance inspection or before a near-sighted officer, but not otherwise, for his coat was of light green and its lapels of strawberry hue, but still the buttons and epaulettes were there, as were the vanilla-hued trousers, and the boots, which were represented in deep and enduring brown. In the making of French ice cream a copper kettle, connected with machinery, is made to revolve in a wooden tank containing salt and ice. No cover is attached to the kettle, and the cream is kept in motion and clear of the sides by an attendant who is armed with a long stick. This man cleaves to his task until the cream is frozen to the proper consistency. Very interesting was the process of making a biscuit glace. Handy by the expert was a big copper bowl. It would probably have held two or more gallons. Into this was emptied several quarts of raw cream. Then a lusty-looking individual with a bulbous brush formed of wires approached the bowl. As he drew near its edge he halted, nerved himself for an effort, and raised his arm. The wire brush descended upon the cream with a rotary motion, and the implement went through the liquid with a loud and spiteful swish! Again and again this was repeated, and faster fell the strokes until the cream had lost all its original semblance. Now it looked not unlike a monster ball of cotton in its snowy fluffiness, and occupied half again as much space in the bowl it had done at the beginning of the operation. It was evidently hard work for the man who was doing the lashing, for he got very red in the face, and beads of perspiration stood upon his brow when he had finished the task, even if it was zero weather within ten feet of that very spot. Next the cotton like ball was sweetened, flavored and frozen. Then a mould shaped like half a watermelon and ices of varied colors and flavors were produced. Into each rib of the mould went the ices, no two a kind being in adjoining ribs. Then enough of the frozen cottony ball was placed in the mould to fill it, and, after having been covered, it was firmly frozen in a freezer. That's about all there is of it, for the next thing to be done is to slightly warm the mould, remove the delicacy within, and, after feasting the eyes upon thispoem in sweets, eat it. In the flavor manufacturing department fresh revelations were in store. There vanilla beans, chopped almost as fine as sawdust, had been put in glass jars with granulated sugar and the air excluded. On the shelves of a cool, dark closet the vessels were arranged, and there they are left until by a peculiar natural process a thick, ropy syrup is evolved. This is then taken to the boiling room, where it is boiled strained, and all impurities removed. It is then ready for use in the cream. That delicate shade of green similar to that variety of French cream known as pistache, is afforded by the meat of the pistache nut. Although the nut is imported from Europe, its rich heart is ground in this great ice cream cavern, and thus its oil is obtained, which, when added to the cream, whipped in and frozen, gives the article its rare and lovely tint. Of course it takes a deal of time and much labor to do all this, and it has to be done carefully and well, but the work is performed by trained, conscientious men. Many thousands of lemons are also used in this factory in the course of a season in the manufacture of lemon syrup. No part of the fruit is discarded save the seeds. Even the rind is preserved, and after all the juice has been squeezed from the pulp the skin is grated and made to yield that pungent essential oil for which the lemon rind is noted. As in the case of the vanilla bean, this product is carefully mixed with sugar and then boiled and strained. When the work is done the syrup is richness itself. Through various passage-ways and around many sharp corners the party proceeded, until it reached the long ice storage room. For a considerable distance this extended under the sidewalk, and it was crammed to its roof of glass, iron, and flagstones with cakes of ice. It is almost impossible to conceive how cold it was amid those glistening cubes, consequently the explorers did not remain there long. At the entrance of the vast vault a halt was made to view the action of the powerful ice-crusher. Into the capacious maw of that voracious machine a big, broad-chested, sinewy man was sliding blocks of ice with the aid of a pair of tongs. With a crash they fell against teeth of steel, affixed at regular intervals to a swiftly whirling steel cylinder. Crunch! crunch! went the teeth as they tore the ice to pieces. Patter! patter! went the fragments as they dropped in an unceasing silvery shower on the floor below. Each particle had passed through a steel comb in the machine before emerging, and was so graduated that it was but little larger than a peach. One hundred thousand pounds of ice are fed to that crusher every day, yet it is always hungry for more, and the feeder is always tired when his day's work is done, and so is the man who shovels away the pieces. Beyond the gleaming heaps under the ice-crusher were other nooks and corridors. In a roomy alcove reached by a somewhat circuitous route rose tier upon tier of empty tubs. Each one had been scraped, washed and scalded until it was a symbol of sweetness and was only waiting to do duty in its turn. Further on was another recess in which were myriad cans of cream with that day's aroma of the dairy still clinging them, while behind and on their right and left flanks were

casks of pure fruit juices, all the result of infinite labor. Scarcely less interesting and instructive were the salt vaults of mammoth size, filled to the brim with salt from the Retsof mines in this State. Other varieties are sometimes employed among which are the Lisbon, Cadiz, Onondaga and Syracuse brands, but the Retsof goes further, eats away the ice more quickly, and so achieves desired results in a briefer space of time. At a distance the heaps of salt rising above the vault look not unlike miniature mountains of dirty white sand, but upon closer inspection the irregular formed rock crystals are plainly visible. These are stained and made dingy by percolations from the soil beneath which the mineral is found, but the dirty salt is just as effective for the purpose for which it is adapted as it would be if snowy white. The vaults are never permitted to become empty. Damp days to the ice cream maker are days of sadness and dulness; wet days make him miserable and wretched; but when it rains his spirits sink to an indescriable depth. But, notwithstanding the fact that less ice cream is sold on such days, the cream remaining in stock requires as much attention as a teething infant. Each can has to be tucked away in a wooden bed, and made nice and cold with thick coverlids of salt and broken ice, otherwise they would soon become unsalable. Then these iron and zinc clad charges demand the unremitting attention of one man, and he attends to his task with the fidelity of a mother, although he does it with a scoop shovel. Usually, however, all ice cream made in the morning is sold in the afternoon of the same day, and that turned out in the afternoon is disposed of by the following morning. None is manufactured in the expectation of future emergencies. If a big order is received so much the better, and everybody toils with increased zest until the order has been filled. Those big order days, like roasting hot days, when humanity above ground is half grilled and frizzled, are days of joy, smiles and dollars to the ice cream man. Repassing through the packing room and its crowd of white-robed workmen, where the temperature of the place is not far above the freezing point, the engine room was disclosed. Everything looked bright and neat but, phew! how hot it was there! It was certainly 90 degs., and in the shade at that. Next came the reflection of a burst of flame, seemingly from an abyss. In the sub-cellar, reached by a steep flight of stairs, was seen a man working like a demon at the mouth of a blazing furnace, which he was feeding with coal. Stifling heat waves were wafted upward. Yet while the visitors hurried away, the demon fireman worked on, bathed in a ruddy light. Again at the mouth of the cavern the blighting breath of July was felt upon the cheek, and once fairly outside the reaction came, and perspiration, long pent up, began to ooze from every pore. That hour's trip in that icy realm was one to be remembered. Statistics show that, as a local commercial industry, ice cream making is from year to year assuming greater proportions, and now gives employment to 1,500 men and women. At least 150 bushels of rock salt and as many tons of ice are used every day by the larger firms, yet the business was only inaugurated in this country in 1851, at which time two small firms made and sold from 50 to 100 quarts of this frigid luxury in a day. Now there are perhaps twenty large firms and an almost endless number of small concerns engaged in this occupation in and around Manhattan Island, to say nothing of the thousands of households in which the ice cream freezer is an article of furniture. Unprincipled dealers resort to many artifices to avoid the expense attendant upon the purchase of pure cream. Some of these employ boiled milk into which is stirred the yolks of eggs, while others make corn starch and milk answer their purposes. Sometimes, not content with these studied deceptions, they not only refrain from using fruit juices or even fruit extracts in flavoring, but introduce harmful chemicals and dyes. Of the latter, aniline is a deleterious and common favorite. Ice cream is of Italian origin, but it remained for a Frenchman, and he the chef of the late Joseph Bonaparte, to introduce it into this country, and he did so in the family of his employer on his estate at Bordentown, N.J. That was in 1848, and from that small beginning the present stupendous business has grown.

TREES AND MOISTURE.

THE FOREST IN THE ECONOMY OF NATURE.

It is a strange fascination that draws man to the forest; a glorious sensation that steals over him as he stands in its cool leafy shade, through which the sunlight peers only coyly, gilding in spots the stately stems. How powerful a charm is exercised by the forest over those capable of appreciating the beauties of nature, can only be measured by the depression, and longing, and sense of desolation which fills them in a treeless region. From the dawn of history until now, man has everywhere signalized his settlement by a purposeless onslaught on the forest with axe and brand, until there was nothing left to destroy. Granted that in thickly populated countries the first need of existence is the spread of agriculture; that there is no place for forests in the fruitful plains and rich valleys, and that the path of progress is hewn by the pioneer who with his axe prepares the way for the plough; there is nevertheless a need for the forest in the economy of nature, and a place for it in the most densely peopled countries. Excepting only in naturally moist countries like Holland and Denmark, agriculture itself is dependent upon forests for its successful prosecution. Through the ignorance and avarice of man wide regions of once fertile country have been converted into arid wastes by the destruction of the forests. The most terrible forest destruction in modern time has been perpetrated by the Spaniards and the Anglo-Saxon peoples, among which latter we must reckon the people of the United States. Too late, alas! It is only in quite recent time that man has learnt to appreciate the vast importance of forests in the economy of nature. Forest destruction implies not only lack of timber and fuel, but involves other and still more serious consequences by its influence on climatic conditions. Forests are the sources of springs; they regulate the flow of the streams; they temper the suddenness of changes in temperature, and arrest the destructive force of the tornado; they absorb the rainfall in their spongy floor, and by its equable distribution regulate the moisture in the adjacent soil and atmosphere. By these means they exercise an important influence on the health and comfort of humanity, on agriculture, on trade and commerce. With the destruction of the forests the conditions gradually become unfavorable for man and beast, and progress is arrested. It is only in moderately warm and moist climates, such as Great Britain, Denmark, and Holland, that the consequences are less pernicious; but where the tropic sun's rays beat fiercely upon the earth, or in inland regions where no fresh sea breeze wafts its moisture upon the parched vegetation, where the fierce storm speeds with untrammelled fury after the treeless region, there the climate may become rude and inhospitable beyond endurance. In the rainy season, the waters rolling off the parched slopes, overflow the brook and river beds, submerge the valleys with floods, and retreating as rapidly as they rise, the once noble rivers are reduced in summer to shallow streams, with scarcely water enough to drive a mill-wheel or float a canoe. With the disappearance of the forest the fruitfulness of the land vanishes, and the health and well-being of the inhabitants is prejudiced. But in spite of the manifold terrible experiences which man has had in this direction, there is no general practical recognition of the relation of cause and effect, and it is hence ever a duty to insist emphatically on the eminent importance of forests in the economy of nature. In the first place it is a function of all green plants to withdraw carbonic acid from the atmosphere, utilize the carbon for building up their own substance and set free the oxygen. This oxygen is the first necessity of existence of animal life, while carbonic acid in excess of the normal quantity in the atmosphere is fatal to it. Forests take in the carbonic acid which animals are incessantly generating, and it is calculated that the amount thus absorbed would suffice to render the earth uninhabitable in the course of a few centuries if all vegetation were destroyed. Animal and vegetable life are essential to each other's continuance; animals replace the oxygen they breathe with carbonic acid, and vegetation is necessary to restore the equilibrium. In this process forests perform the lion's share of the labor, since area for area they carry a thousand times the material engaged in purification of the atmosphere, that a cultivated crop does. Of equal general, and of still greater local, importance is the function of the forest in the storage of water and feeding of springs. There is no sufficient ground for the conclusion that the existence of forests increases the rainfall, excepting on hill-tops where the passing clouds, impeded in their course, are condensed into rain; but all the rainfall of the region absorbed by the forest floor, instead of flowing directly back by the rivers to the sea, is re-evaporated and condensed locally as dew, and this phenomenon occurring constantly, is equivalent in its effect on vegetation to a considerably enhanced rainfall. Forest-clad hills are the sources of supply of the springs in the plains below, and, by the retention of their moisture, they are no less the source of rivers which, by the economy of the forest, are maintained in perpetual flow.—*Die Natur, May* 30.

VACATION PREPARATIONS.

ESSENTIALS FOR A GIRL'S SUMMER TRUNK.

If you wear a fluffy bang, you want your alcohol lamp. If you wear laced shoes, you want a dozen pair of shoe strings. If you varnish or polish your shoes, you want a new bottle of blacking. If you are inclined to sunburn, you want a pot of strawberry cream or some cold cream. If you are fond of reading, you want your favorite books. If you ever use pins, you want a block of black ones and a paper of white ones. If you are a good girl and mend your clothes, you want some spools of thread, your needles, your thimble and some buttons. If you make yourself sweet with infant powder and a puff, you want a sealed package of powder. If you use bonnet pins to fasten on your hat, you want a dozen of them. If you are inclined to be ill tempered and petulant, you want unlimited patience. If you are inclined to be careless and inconsiderate, you want a large package of energy and friendliness. And if you are lacking in politeness, then you want to remember that surely she who claims to be a Christian must, before everything else, be gentle in her manners. —*Ladies' Home Journal.*

LARGEST BAY.—The largest bay in the world is Hudson Bay, measuring 850 miles north and south by 600 miles wide.

CALIFORNIA FRUIT.—Some of the fruit experts of California call attention to the fact that while the wheat crop of that State did not materially increase from 1880 to 1890, the fruit output increased more than thirty times, and is still rapidly growing.

FENCES AND ELECTRICITY.—A singular complaint comes from the fire insurance companies. It relates to large losses in the farming districts on live stock, due, as reported by the farmers, to lightning in connection with barbed wire fences. Most of the animals killed in this way were near the wire fences at the time, and it is supposed the metal acts as a conductor in a degree sufficient to largely increase the risks. Insurance men believe, however, that many cattle reported as killed by lightning were in reality killed by injuries received in coming into violent contact with the barbed wires.

GERMAN COOKERY.

A GLIMPSE INTO THE NATIONAL DISHES OF THE WORLD.

(*Concluded from page* 230.)

In the present number we conclude our selection of German dishes, dealing mainly with the lighter department of sweets, cakes, and pastry. Among these dishes there is an absence of those violent contrasts and surprising incongruity of ingredients noticed in our introduction to the more substantial dishes of Germany. In the domain of the Torten, the Nudeln, the Kaltschalen, and Kuchen generally, Germany may be said, if a culinary levity for once be permitted, to "take the cake," and that cake, if made by a German, is sure to be a good one. In all departments of cookery the German is not only ingenious, original, but eminently conservative. German cooks adhere to the ancient national German dishes as the German printer adheres to the ancient Gothic character of his types; the one objects to French-made dishes as the other objects to Roman lettering. If the French had not had the start of a century with their *cuisine*, it is odds but that Europe would to this day be eating *Bier Suppe mit Kummel Sauerkraut* from St. Petersburg to Lisbon, instead of *consomme a-la-financiere* and *choux fleur au gratin*.

HARING KARTOFFELN (STEW OF HERRINGS AND POTATOES).—Boil potatoes in their skins, not too soft, peel and slice them, and keep them warm. Cut up an onion and put it in a stewpan with a piece of butter or some very thinly cut fat bacon. When the onion begins to turn yellow, dredge it with flour; add a little water, salt, pepper, two or three tablespoonfuls of vinegar, and a bay leaf. Leave this to simmer. Meanwhile, wash two herrings, take the bones out, cut the fish into small dice, add them to the sauce to simmer a few minutes, then put in the potatoes. Stir all together gently, so that the slices of potato are unbroken. Add a piece of butter and a little to moisten the stew, and serve quite hot.

KARTOFFEL OR SCHUFF NUDELN (POTATO NUDELS).—Boil some potatoes and let them get quite cold before they are used. Grate them on a coarse bread-grater. To a plate of grated potatoes add a quarter as much flour, and make of this mixture a dough with two beaten eggs and a piece of warmed butter. Roll pieces of the paste into *nudeln* the size and shape of a finger, but a little pointed at both ends. Make a piece of butter hot on a flat stew-pan; put in the *nudeln* and shake them occasionally till they begin to color. When done, beat up two eggs with a little milk or cream, pour it among the *nudeln* and shake them up in it. Let them strain and serve.

ZUCKERSCHAFEN (YOUNG PEA PODS).—These are the flat pods before the peas are grown. String them like beans, snap and skin the shells, and put them in a stewpan with a little butter, a little gravy or stock, salt and pepper. Either a small onion, a little mint, or a sprig of thyme may be steamed with them if approved. They must only be moist enough to cook soft, without burning. These are excellent with lamb, veal or spring chicken.

SAUERAMPFER (SORREL).—Pick the leaves from the stems, wash and drain them well, and put them in a saucepan with a piece of butter to stew in their own juice. Make a thick sauce of flour, butter, gravy, or water, and the beaten yolks of two or three eggs; add it to the sorrel. Serve with roast lamb, cutlets, *fricandeaux*, or pancakes.

BAIERISCHES KRAUT (BAVARIAN CABBAGE).—One or two full-grown white cabbages must be washed and stripped of their outer leaves. Quarter them, cut out the stalks, and slice the cabbage across in strips, as thin and fine as possible. Sprinkle among the shreds some salt and a few caraway seeds, and let it stand for an hour. Make two or three ounces of butter hot in a stewpan; put in the cabbage, and let it stand till it is soft and yellow. Then pour in a glass of white wine, and half the quantity of vinegar—there must not be enough of the latter to taste distinctly acid. Cover close, and let it stew slowly till quite soft. Half an hour before serving, dredge in a little flour and stir it well.

SAUERKRAUT—To make this famous national pickle the finest and hardest white cabbages must be chosen; it improves their color to let them lie heaped together in a cool corner for several days before they are used. The cutting is usually done with an instrument called a *kohlhobel* (cabbage plane), but a large knife will do equally well. Throw away the outer leaves of the cabbages, halve and quarter them, and cut out the stalks and outer ribs of the leaves. Begin at the top of the head to cut them across in very narrow strips. Have ready a well-seasoned oak barrel or pickling tub, or an earthen bread-pan would do. Cover the bottom of the vessel with clean uncut cabbage leaves, and throw in the cabbage as it is cut, sprinkling it well with salt, equally dispersed, as it is thrown in. Some cooks scatter in a few juniper leaves or caraway seeds. As the shred cabbage is put into the tub it should be pressed down hard with a club, When all is packed as close as possible strew a little salt over the top, cover it with a few cabbage leaves, and then with a clean linen cloth. Put on it a wooden lid that will fit inside the vessel, and lay on this a heavy stone. The "kraut stand" must not be put in too cool a place until fermentation has begun; this may be known by small white globules forming on the brine, which ought to appear above the kraut after two or three days. If this is not the case, boil salt and water, let it get cold, and then pour it over, but this must not be a strong brine. A good handful of salt is enough to allow for a large bucket or firkin of cut cabbage; too much prevents fermentation. In a fortnight the cloth on the top must be well washed in cold water and spread over again. At the same time the leaves on the top must be well rinsed or renewed. This washing must be done once every week. In two or three weeks the kraut is sufficiently pickled for use, and will keep good for a year.

SAUERKRAUT.—To cook sauerkraut.—Put a good-sized piece of butter in a saucepan, let it melt, then put in half the sauerkraut intended to be used, from which the brine must be squeezed as it is taken out of the tub, and on it place the meat intended to be cooked with it, either a piece of ham or bacon, soaked and pared, pork, or any kind of sausage. Lay over it the other half of the kraut, pour in a glass of white wine, and add occasionally a little water to moisten; cover close, and let it stew gently until the kraut is soft and yellow. Take out the meat when sufficiently cooked. Dredge in a tablespoonful of flour to give smoothness; let it stew half an hour longer, they lay in the meat again to get thoroughly hot. Stir the kraut occasionally with a wooden spoon, and be careful that it does not burn. It is excellent warmed up again with some other meat the next day, or a day or two after. Indeed it cannot be cooked too much, and requires at first from two and a half to three hours' stewing. Sauerkraut, as an accompaniment to smoked meat, roast pork, sausages, etc., may be cooked as above without the meat; in that case make a flour and butter thickening to stir in half an hour before serving. A finely minced onion is often added in the stewing, and is an improvement.

SCHWEEM KLOSSE (FLOATING KLOSSE).—Six tablespoonfuls of flour and three eggs, well beaten, must be stirred into one-half pint of milk. Put two ounces of butter in a stewpan and let it melt; pour in the batter and stir it constantly till it boils quite thick; then take it from the fire and stir frequently till nearly cold. Mix well with it three more eggs and a little salt, and then spread the mass half an inch thick on a flat dish. When required for table, take up small *Klosse* with a spoon and put them gently into boiling water to cook for five minutes. Take them up with a strainer and put them into the tureen of soup.

SCHMAROLLEN.—Let a pint of new milk boil, stir in one ounce of sugar with flour enough to thicken it, and boil till the mixture ceases to adhere to the sides of the pan. Then turn it out and, when cool, stir in four well-beaten eggs. Have one and a half pints of milk boiling in a stewpan, and, with spoon dipped each time in water, cut klosse out of the mass and simmer them in the milk a few minutes. Put them all in a dish, put two ounces of butter on them, and bake them a pale brown in a quick oven.

APFELSINEN KALTSCHALE (ORANGE KALTSCHALE).—Peel off the yellow rind of six oranges as thin as possible; throw the peels into a half pint of water with plenty of sugar, and when this is dissolved add one half pint of light white wine. Remove the white skin from the oranges and cut them in thin slices. Lay them in a glass dish, one half over the other in a circle, with sugar strewn between and over them. Put a few slices in the centre, and then pour over the syrup, leaving the yellow peel as garnish. Set the dish in a cool place till it is required and serve sponge cake or fancy biscuits with it.

DAMPFNUDELN (STEAMED EGG DUMPLINGS).—Ingredients: One pound of fine flour, three ounces butter, two eggs, one ounce of sugar, one quarter pint of good milk and cream, one ounce of dry yeast, or a small cup of fresh yeast, and a little salt. The milk must be lukewarm and well mixed with the yeast; then add the sugar, the eggs well beaten, and the butter, which must be warmed. Mix in the flour and beat the whole till it is light and spongy; cover it with a cloth and let it rise by gentle warmth. Turn out the dough on a well-floured pasteboard; cut off egg-sized pieces and lightly roll them into round balls or ovals; leave these on the pasteboard to rise again. Put two ounces of butter in a broad flat stewpan, with a dessert spoonful of sugar and milk half an inch deep. Let this boil; take up the cakes gently with a slice and lay them close together in the boiling milk. Cover with the lid of the stewpan and put them in the oven till the milk is nearly dried away, and they have a nice yellow crust. Take them carefully apart, serve with any sweet sauce, fruit or syrup. It is better to bake them over a stove, or with live coals on the lid of a stewpan, instead of putting them in the oven.

NEUN-LOTH PUDDING (A CELEBRATED RHENISH PUDDING).—Stir half a pint of milk into four and a half ounces of fine flour, and four and a half ounces of powdered loaf sugar. Put into a stewpan four and a half ounces of powdered loaf sugar. Put into a stewpan four and a half ounces of butter and half a pint of milk, and when this is hot and the butter melted, stir in the mixture of milk and flour and keep it well stirred over the fire till it boils and thickens; then turn it out in a pan to cool. Stir in the yolks of nine eggs, four and a half ounces of almonds blanched and pounded, and lastly, the nine egg-whites whisked to a stiff froth. Stir all briskly together, butter a mould or basin, fill it with the mixture, and boil the pudding an hour and a half. Be careful that the water does not cease boiling. Serve white wine sauce with the pudding.

MARZIPAN (MARCHPANE.)—Blanch and pound together one pound of sweet and one ounce of bitter almonds, adding now and then a few drops of orange-flower or rose-water to keep them from oiling. They must be pounded quite fine. Put the almond paste into a stewpan with one pound of powdered sugar, and stir it over a slow fire till it forms a smooth paste that will receive the impression of a finger without sticking to it. Then turn it on a pasteboard well strewn with sifted sugar; mould it into an oval form, and let it cool for use. It may be rolled out thin, cut into stars, rings or round cakes or, any little fancy shapes. Put them in the oven to bake slowly a pale yellow. Or, roll out the paste as thin as possible; cut it into pieces of equal size, or cut out round cakes. Lay over one another with a layer of preserve between, and brush it over with white of egg. Stamp out little

ornamental devices or thin rings, and lay them on the large cake; then brush them over with white of egg glazing. Put it in a slow oven to color a delicate yellow.

LINZEN TORTE.—One half pound of sweet almonds, blanched and pounded, one half pound of sifted sugar, one half pound of butter, three well beaten eggs, and three-quarter pounds of flour must be mixed lightly in the manner of tart paste, rolled out to the thickness of the third of an inch and spread on a flat-buttered tin. Spread over this a thick layer of apricot or other preserve, and over it put either a thin cover of the paste or narrow strips of it to form a network, then lay a thin border of paste round the edge and notch it. Brush the *torte* over with egg, dredge it with sugar, and bake it a pale color in a moderate oven.

CHEAP CANDY.

SOME POINTS REGARDING THE QUALITY OF CANDY.

"Never expect to get any kind of pure candy for less than 40 cents a pound." It was my friend the foreman of a big candy manufactory who spoke, says a writer in the New York *Herald*. "The nuts, the flavoring and the labor on all bon bons and fancy candies, make the actual cost to the manufacturer at least 30 or 35 cents a pound. Don't think that we are in the business for love, and that you can get good candy for 20 cents a pound. We are not selling gold dollars for 50 cents." "What is the purest candy made—the least harmful for children to eat?" "It makes no difference, all fine candy is equally pure. By pure candy I mean that made of the best refined sugar, fresh fruit flavorings, vegetable coloring and fresh eggs. All that costs. Pistachio nuts alone now cost ninety cents a pound and pure black chocolate thirty to forty cents. So you can see why candy to be good must cost at least forty cents a pound. There are imitations of all these ingredients on the market, and they are used extensively by the cheap candy houses. They are put together so cleverly, too, as frequently to deceive the most sensitive palate. But they can't deceive the stomach." "Marsh mallows are as little injurious as any candy, are they not?" "Oh, no, half the marsh mallows are frauds. The real marsh mallows are made simply of the whites of eggs, sugar and gum arabic. A compound which we call 'lily squash' is used to imitate this with. It is made up mainly of glue and flour. The glue is very indigestible and, of course, these fake marsh mallows are very bad things to eat. Equally, of course, they are cheap. Nearly every mother seems to think that if they give their children marsh mallows it's not like giving them candy; that they are harmless. That's all nonsense. If candy is at all injurious to children, marsh mallows are just as harmful as any other bon bon."

ANGEL FOOD.

AN ENGLISH WRITER DESCRIBES ITS COMPOSITION.

From the *British Baker* is taken the following opinion on the "angel food" industry: "In spite of all that has been said to the contrary, these cakes are an undoubted importation from America, where a few years ago they were in very great demand, but of late years their sale has very much fallen off, and they will, no doubt, at no very distant date die a natural death. At their best they are somewhat dry and insipid, and being very troublesome to make, their sale has not been in any way pushed." The writer proceeds to say that it is the most particular cake in the world to make; the whick and the pan must be entirely free from grease. He then gives the following recipe from a Montreal baker: "One quart whites of eggs, two pounds pulverized sugar, one pound flour, two ounces cream of tartar. Sift the flour and cream of tartar well together two or three times through a flour sieve, beat up the whites in a clean towel with a wire egg-whisk, the same as for meringues, till they will bear up an egg, then add a spoonful of vanilla extract, and mix the sugar in with the whisk. Then stir the flour gently in with your hand, divide into cakes, and put into pans of suitable size, and bake in an oven that is not too hot, but, if anything, rather colder than for ordinary large cakes; and when they come from the oven do not take them from the tins or pan, but turn them upside down upon a wire, and stand them in the rack where the air will get at them. Prepare the tins exactly the same as for sponge-cakes. The cakes require very careful baking; they will take from twenty to thirty-five minutes, according to size."

DOMESTIC DIETETICS.

SPECIALLY PREPARED. FROM PRACTICAL TESTS, FOR THE LADY READERS OF THE "AMERICAN ANALYST."

SEASONABLE FOOD.

August.

GAME AND POULTRY.—Pigeon, chicken, duck, woodcock.

MEAT.—Beef, lamb, mutton, ham, kidneys, liver, sausage, veal, venison.

FRUITS.—Cherries, raspberries, huckleberries, melons, gooseberries, blackberries, peaches, pears, tamarinds, bananas, pineapple, grapes, plums.

FISH.—Anchovy, bass, bluefish, blackfish, cod, eels, crabs, clams, flounders, halibut, herrings, lobster, mackerel, mussels, porgie, prawn, salmon, turtle, trout, sturgeon, whiting, weakfish, rockfish.

VEGETABLES.—Beans, beets, cucumbers, cabbage, carrots, cauliflower, corn, egg-plant, lettuce, onions, parsley, parsnips, potatoes, squash, shallots, spinach, turnips, radish, rhubarb, tomatoes.

PRACTICAL RECIPES.

SQUASH SOUP.—Cut a medium sized squash in pieces about two inches square, without removing the rind; steam or bake these half an hour; when cold, rub through a sieve twice. Put into a frying-pan an ounce of butter and a table-spoonful of minced onion; when the onion is a yellow color, add a pint of hot water or stock, season with part of a long red pepper, half a teaspoonful of salt, a leaf or two of celery, three cloves, and a very small bit of mace. Simmer twenty minutes and strain. Wet a teaspoonful of flour with a little cold water, and when free from lumps add to the strained liquid. Simmer until smooth, and add to it a quart of solid squash pulp. Put on the range two quarts of hot water or soft stock. When warm, whisk the squash into it. Scald a pint of rich cream and beat it into the soup. Season to taste, and serve with bits of toasted bread.

TONGUE JELLY.—Take a pickled tongue, boil and peel it, and when cold slice it very thin. Take two cupfuls of the water the tongue was boiled in, a cup of brown gravy or good rich stock, two good table-spoonfuls of vinegar, and a box of gelatine soaked for two hours in just enough water to cover it. Put these together; add two cupfuls boiling water; mix well and strain; season. Let it cool, then fill a mould with alternate layers of jelly and tongue, and set on the ice to stiffen.

ORANGE MARMALADE.—Take for this bitter or Seville oranges; soak them for fifteen minutes in just enough boiling water to cover them. Quarter them, and remove the pulp with the fingers. Put it in a separate dish, cut the rind in thin strips with a sharp knife, and put it in a preserving kettle; pour over it sufficient cold water, and allow it to boil until tender. Drain it through some coarse netting. Cook the pulp for fifteen minutes, and strain through the netting, which will clear it of all skin, seeds, and pith. Put the pulp and rind together and weigh them. Add sugar, a pound for every pound of orange. Return the mass to the fire and boil, stirring smartly. Try from time to time to see if it jellies. When it does, it is done.

ANCHOVY TOAST WITH POACHED EGG.—Cut slices of home-made loaf bread a quarter of an inch thick, trim them neatly and toast them in the oven; when slightly colored, spread a thin coating of anchovy paste or essence on the slices, add a poached egg to each and serve.

MILK CHOCOLATE.—Melt six ounces chocolate, add one quart milk and sugar to sweeten, beat up the yolks of five eggs with a cup of cold milk. Stir the chocolate until it is scalding hot, then pour it upon the eggs. Flavor it with vanilla and beat very fast until it froths, then serve at once.

CHOCOLATE PIE.—Make a four egg cup cake and bake it in a pan, a little deeper than an ordinary layer cake tin. When done, split it with a coarse thread and put between the layers the following mixture: one cupful sugar, yolks of two eggs, one square chocolate, two large table-spoonfuls boiling milk, scrape the chocolate, mix it with the sugar and add, gradually, the milk, then the eggs, simmer for a moment or two, stirring carefully, add some vanilla and take form the fire, eat cold.

PUDDING SAUCE.—Beat up the yolks of six eggs, add to them four table-spoonfuls sugar and four of butter mixed together. Have a pint of cream boiling, add to it your eggs, then put on the fire and stir until well mixed together. Add a wineglassful of brandy and a little nutmeg.

LIFE'S ROMANCE.

THE STORY OF A DIAMOND RING.

Twenty-three years ago last February, as a Newark, N. J., jeweler was about to close his store one stormy night, a shabby young man entered and offered to sell him a gold ring containing a diamond stone surrounded by a circle of smaller gems. He asked $150 for the ring, saying it was all he had in the world. The man declared he must dispose of it that night, but his anxiety made the jeweler more fearful, and at last he firmly refused to have anything further to do with the matter until the next day. On the morrow the visitor came again. The merchant bought the ring. He reset the stone in a lady's ring, and a month later it was carried away by a happy lover, and it sparkled on the hand of a blushing bride in high life soon after. Ten years later the same jeweler paid a half-starved, shivering woman exactly what her lover had paid for the ring a week before her marriage, and as she led away her golden-haired girl she felt that she was rich with what she would have thrown aside a cadeau before. The next purchaser was a portly old gentleman, who gave the stone to his young wife, whom he had taken from her school-books to assume the management of a grand old mansion. It was just two years ago that the old gentleman, still hale and hearty, entered the jeweler's store, leading by the hand a bright-eyed little fellow, whom he introduced as his son and heir. Then he stated the object of his visit. He said the ring reminded him too much and too plainly of the fair young mother who never saw the face of her baby boy.

OZONIZED BRANDY.—It has long been a disputed point whether science possesses any absolutely certain method of aiding nature in the development of ethers and bouquet in spirits; in other words whether it is necessary for a long time to elapse before brandy, whiskey, rum, etc., can be rendered fit for consumption by the action of age. M. Teilliard, of Jarnac, near Cognac, appears to have solved the problem of rapidly maturing brandy by treating it with ozone. In France, England, Russia, Sweden, Switzerland, and other countries, competent authorities have declared in favor of ozonized brandies.

DÆDALUS IN SCIENCE.

ELECTRICITY IN THE PLACE OF WINGS.

A belief is current that we shall fly some day by means of electricity, although no definite method of employing this great agent has been devised. There are two methods suggested for the application of electricity to flying. One is a modification of the so-called telpherage system, which has been tried in England and Wales for the purpose of transporting small packages on a kind of aerial railway. An electric motor runs on a species of elevated railway at a great speed, and, since the railway can be practically an air-line, deep cuttings, tunnelings, and sharp curves can be avoided. It is but a step from this method of aerial locomotion to that of a system which proposes to employ air ships. Suppose, for instance, that a suitable balloon should be provided with an electric motor properly fitted with screws, vanes, and rudder, and that a powerful electric current should be led to this motor by means of trolley wires which slip, or the ends of which run along elevated wires such as are now used in certain double trolley electric railroads. Such an air ship would have certain advantages over the electric railway on the ground. It would have the advantage of the steamship—free to go through a wide stretch of air, unhampered by conditions of stability of roadway, or limitations of curves and gradients. It is true that it would have head winds to contend with. This obstacle the steamship has also to encounter on water. To the believer in the possibility of flying, however, this method seems humiliating. It is not flying; it is telpherage. The aeronaut wishes to cut loose from the earth entirely, and to compete with the birds in an element which has been theirs for countless ages. The method which is thought to be the coming one, is that based upon the employment of storage batteries. A light storage battery, capable of containing at least one horse-power, is to turn an electric motor in a suitable air ship, and by the means of a light motor the problem is to be solved. It is generally conceded, however, that if we are to fly by electricity, we must first be shot off some suitable height to attain the requisite initial velocity. Great hopes were excited when the Faure storage cell was invented. Here was something which the world had long been waiting for, and many prophesied that it would revolutionize methods of locomotion. Unfortunately these hopes have not been realized. The weight of the average commercial lead storage battery is about 100 pounds per horse-power per hour. If one wishes to run a motor for six hours, the battery should be charged for ten or twelve hours; and, under the most favorable conditions, 80 per cent. of the current which is used to charge the battery can be recovered by its performance. In a certain limited sense, the lead storage battery is a success, but its weight is a serious practical difficulty. A new cell was invented two or three years ago by Desmazures of, approximately, only half the weight of the lead cell, and the Americans Waddell and Entz have modified it in certain slight but important particulars, producing a remarkably efficient accumulator. The saving in weight of the battery over the lead storage battery is about 1,500 pounds per car. But although the weight of the storage battery has now been reduced one-half, it is still very great. It is not probable that the future bicyclist of the air can support himself and progress with less than one horse-power at his command. With 100 pounds in his battery and 100 pounds in his motor added to the weight of gear, wings, and rudder, the electrical aeronaut would be heavily handicapped even for a short trip. Even if a lighter storage battery should be invented, the weight of the electric motor is still very great. What invention may accomplish in the way of lightening it, no one can predict. At present, electrical motors are too heavy to be seriously considered for the propelling agents of flying machines which are not in part balloons. It is the belief of many who have studied the subject, that telpherage is the only method by means of which man will rise superior to certain mundane limitations; we, therefore, return to the consideration of a balloon ship driven by an electric motor which is driven by a current fed to the motor, by a trolley wire. This method of flying, although ignominious to one who desires to cut himself entirely free from all connection with the earth, still seems to be a possible solution of the endeavor to use the air as steamships now use the water. The new method of step-up and step-down converters would admit of comparatively fine wire being used to convey the electrical current from the wires on the earth through the trolleys to the balloon ship. With flying machines, the problem of "stepping down" safely still puzzles the aeronaut whether he proposes to employ electricity, or some other source of power.—*The Chautauquan.*

THE TEST OF TIME.

"What's one man's meat is another man's poison," is a truth which is demonstrated by the history of medicine. Every day some preparation is put on the market whose only recommendation is that it has cured one, two or three people of some serious ailment. It is widely advertised, people buy it from curiosity, its sales grow immense, and for a brief period it is prosperous. Then, as the public discover it to have little or no curative power, its popularity declines and its sales diminish, until its owners begin to lose money and close its manufacture forever. Few indeed of the medical discoveries of the century have stood the test of time. Among those which have may be mentioned the compound iodies, the hypophosphites, and, above all, Ayer's Sarsaparilla. Strange to say, in none of these cases did the original inventor perceive the full magnitude of his achievement. Dr. Ayer, in 1840, in experimenting upon all possible combinations of valuable alteratives and beneficial herbs, had in view the expulsion of all humors of the system, and the rejuvenation or strengthening of the vital organs. At that time, the medical schools were far less scientific than they are now, and taught that such ailments as bronchitis, pneumonia, rheumatism, gout, neuralgia, jaundice and summer rashes were local, and that local treatment was the only thing to be taken into consideration. It was, therefore, with profound surprise that both the public and the faculty saw that Ayer's Sarsaparilla cured all these ills, often, in fact, when everything else failed.

When Dr. Ayer first published the formula of his famous preparation, so that it became the property of mankind, the mystery was not lessened in the least. Only as medical science progressed, and it was discovered that nearly all disease is constitutional rather than local, and that all treatment must be applied accordingly, did the secret of the success of Ayer's remedy become known. Thus in the case of boils, which seem purely local, there must be local applications to allay the inflammation and to diminish the pain, while on the other hand there must be a constitutional treatment of the Sarsaparilla and some aperient to cleanse the system and to tone up or stimulate the vital functions. Without the latter the boils continue to appear until the vitality is lowered to so great a degree as to cause the body to suffer until all the impurities are purged away. With the latter, those boils which have reached the suppurating stage go through their development to the end, the half formed ones are slowly absorbed and the incipient ones disappear immediately. To-day when the nature of all disease is becoming so well known as to be a household word, it is found that Ayer's Sarsaparilla is the great general remedy for every ill and disorder whose origin lies in an impure state of the blood, or a lethargic condition of the system. Time has tested the preparation, and pronounced it the best and most efficient weapon against disease possessed by either the practitioner or his suffering patient.

BUSINESS NOTES.

THE RIVAL WORCESTERS.

The conspicuous success achieved by Messrs. Lea & Perrins as producers of the original Worcestershire Sauce has borne the usual fruit, and called into existence clamorous competitors, who are just now making a dead set at the American market where Lea & Perrins' incomparable appetizer is almost as popular as on this side of the Herring Pond. It will be judicious, however, for American hotel-keepers and caterers to accept with the proverbial grain of salt the statements of those who claim for sauces that are comparatively little known on English tables transcendent merits and universal acceptance amongst British epicures. It is of course open for any trader to say that his sauce or soap is "absolutely the best value in the world." The wise consumer appraises such puffery at its real value, makes a comparative test, and settles the question for himself. Certainly, so far as Worcestershire Sauce goes, it is a case of Lea & Perrins' first, and the rest nowhere.—*The Caterer and Hotel Proprietors' Gazette.*

PROFITABLE FRUIT.—Annual profits, ranging from $6,000 to $8,000, are reported in California this season from single groves of oranges and lemons. In one instance the gross receipts were $14,000.

BLASTING BY ELECTRICITY.—A method of blasting by electricity has been tried in Sweden with good results. The means consist of a voltaic arc produced between two carbon rods placed parallel. When the arc is moved close to the spot to be blasted, an intense local heat is created, resulting in expansion that splits the rock.

WHAT CAUSES THE LIGHT.—Prof. Elihu Thomson corrects the popular impression that the luminosity of arc-lamps is due to heated carbon particles. He says that, although there is a steady stream of carbon vapor between the carbons, the light is nearly all derived from the enormously heated surfaces from which the evaporation takes place.

RAPID FIRING.—Dr. Gatling, the inventor of the famous machine-gun, is still engaged in mechanical research. His gun is supposed to have given origin to the destructive French mitrailleuse. From a a capacity of 300 shots per minute, the Gatling gun, as perfected, has now a capacity of 1,200 shots per minute, worked by man power. Recent experiments in the United States Navy developed the fact that there is no limit to its capacity except that of endurance of the parts.

SEEING SALAD GROW.—In Berlin it is said that a new experiment has been tried of serving a dinner party with salad grown before the guests. The following is the recipe tried—it is said successfully—before the Prince and Princess Blucher: "Take good germinating lettuce seed and soak it in alcohol for about six hours, sow it into an equal mixture of rich soil and unslacked lime, and place it on the table. After the soup, water it with lukewarm water, whereupon it commences to sprout immediately."

A RUSSIAN MALADY.—According to the report made by Prof. Tessier, of the medical faculty of Lyons, who was sent in his professional capacity to Russia, for the purpose of taking evidence in regard to the course of influenza there and the various conditions of its evolution, influenza is a normal growth of Russian soil, and when not a raging malady is a smouldering one. Among the contributory circumstances and influences in this line, as enumerated by Dr. Tessier, are the way the people live in winter, locked up in heated houses,—the flatness of the soil, its consequent bad drainage, and universally sodden condition when the April thaw begins—the filthiness of the farmyards, the village streets, and the rivers, which become suddenly swollen, and on falling leave a putrid mud, behind, etc. the microbe of the disease being, in fact, found in this mud, the name given to it being strepto bacillus. A peculiarity mentioned as characterizing this disease is its alliance with this bacillus of pneumococcus, which also lives and thrives in Russian marshes, river mud and village pools.

BIRCH OIL.—Birch oil in a pure state is much heavier than water. Thirteen fluid ounces weigh a pound, and instead of rising to the top of water, it settles to the bottom of it, where, in its action when moved, it resembles quicksilver.—*The Engineer, New York City.*

IRON RUST.—Iron rusts readily in all locations when alternately cold and hot, but particularly when covered with a material which prevents the moisture from escaping freely.

HOPE IT WON'T.—Professor Mayer calculated that, if the motion of the earth were suddenly arrested, the temperature produced would be sufficient to melt and even to volatilize it; while, if it fell into the sun, as much heat would be produced as results from the combustion of 5,000 spheres of carbon the size of our globe.

NEW PRODUCT.—It is stated that an Austrian chemist, Herr Eckstein, has discovered a substitute for celluloid, named hyaline, that is not inflammable It is grainless, odorless, transparent, tenacious, and may be drawn into threads or rolled into films. It is described as composed of colophene, lac, copal, Dammara resin, essential oil of turpentine and gun cotton.

ORIGINAL. No. 43.

Pot Pie Dumplings

BY MRS. DEARBORN,
Principal Boston Cooking School.

Mix and sift together 1 pint pastry flour, 1 heaping tea sp. Cleveland's Baking Powder and ½ tea sp. salt. Beat 1 egg until thick and light, add ½ cup cold water, stir this into the dry mixture, and enough more water to make a dough stiff enough to hold its shape when dropped from the spoon.

Drop the dumplings on a plate a little distance apart and cook in a closely covered steamer for fifteen minutes; or, drop them on top of the boiling stew and cook for the same length of time.

The secret of having them light and tender lies in their not being disturbed while cooking, and in not having much liquid around them, if cooked on top of the stew.—(Copyright, 1891, by Cleveland Baking Powder Co.)

Use only Cleveland's baking powder, the proportions are made for that.

Cleveland's Baking Powder,
Wholesome,
Leavens Most,
Leavens Best.

Thoroughly Soaked

The Woman who has once tried *Pearline* is suited. It suits millions of women who are using it; and millions more are following suit.

It washes easily, to save your clothes and your strength; it cleans thoroughly, to save your time and your temper.

Do you know that with *Pearline* there is little or no rubbing? It is the rub, rub, rubbing that wears out your clothes and wears off your paint. You will like *Pearline*, because it is sure; there is nothing like it, because it is safe.

Beware Peddlers and some unscrupulous grocers will tell you, "this is as good as" or "the same as Pearline." IT'S FALSE—Pearline is never peddled, and if your grocer sends you something in place of Pearline, do the honest thing—*send it back.* 239 JAMES PYLE, New York.

GREAT INCREASE.—The revenue from patent medicines in Great Britain was $210,000, thirty years ago. Within a generation the government revenue from this source has increased five hundred fold, now footing up $100,500,000 annually.

POWERFUL MAGNET.—An electro-magnet for the transport of iron castings has been in use for some time at Pittsburg, and at the exhibition at Frankfort is one capable of lifting a ton.

UNSHAVEN WAITERS.—The Paris waiters still keep up their agitation for liberty to cultivate a beard and a moustache. Several noted restaurant keepers, have declared themselves on the side with the men.

VALUABLE DEVICE.—One of the recent inventions for life-saving apparatus is the pneumatic gun for throwing a line to a ship in distress or to persons in a burning house. The air is admitted from a reservoir to the chamber behind the projectile at a pressure of 2,000 pounds on the square inch.

BLACK BRASS.—Brass may be colored black by repeatedly coating the cleansed metal with a moderately worm solution of nitrate of copper. Heating over a charcoal fire follows. Finally the tone is heightened by rubbing with olive oil.

YANKEES ABROAD.—There are now two thoroughly representative American restaurants in Paris. One is the restaurant Delmonico on the Boulevard des Capucines. This has no connection with the New York Delmonico. At the same time the menu is always an American one, and American gourmets who have dined there say that it is very fairly representative of good American cuisine. The other is the restaurant Marivaux, near the Cafe Anglaise, which is kept by the famous Joseph, the late chef of Mr. Vanderbilt, whose engagement, at the salary of an ambassador, made such a stir in the newspaper world some time ago. It has been this season the fashionable rendezvous of all Americans over there. The general opinion is that it is the best place in Europe for genuine American cuisine. Joseph is specially successful in the preparation of American pastry.

DYNAMITE PROJECTILES.—A recent departure in firing dynamite or other high explosives in a shell and from an ordinary gun, has recently met with great success in Manchester, England. Mr. J. E. Bott is the inventor. Instead of the cumbersome machinery necessary to furnish the compressed air to drive the projectile, Mr. Bott supplies a shell containing highly compressed air in its rear portion. The gun used is a breech-loader smooth-bore. When the shell is entered the action of firing forces a pin inward at the base of the shell, thus tearing a hole in the retaining valve and liberating the compressed air. This drives the shell from the gun with wonderful force. It does not heat the gun, makes scarcely any noise, produces no smoke and has a much greater range than any pneumatic gun yet made, and the absence of fouling enables it to be used continuously.

THUNDER STORMS.—A German periodical gives statistics concerning the frequency of thunder storms in various regions of the world. Java has thunder storms on the average 97 days in the year; Sumatra, 86: Hindostan, 56: Borneo, 54: the Gold Coast, 52: Rio de Janeiro, 51; Italy, 38: West Indies, 36; South Guinea, 32; Buenos Ayres, Canada and Austria, 23; Baden, Wurtemberg, and Hungary, 22; Silesia, Bavaria, and Belgium, 21; Holland, 18: Saxony and Brandenburg, 17; France, Austria, and South Russia, 16: Spain and Portugal, 15; Sweden and Finland, 8; England and the high Swiss mountains, 7; Norway, 4; Cairo, 3. In East Turkestan, as well as in the extreme north, there are almost no thunder storms. The northern limits of the thunder storms are Cape Ogle, northern part of North America, Iceland, Novaja, Semelja, and the coast of the Siberian ice sea.

PORTRAIT OF COLUMBUS.—A Chicago gentleman has purchased in London the portrait of Christopher Columbus, which is generally believed to have been painted by Chevalier Antonio Moro, about the year 1570. It is considered the best likeness of the discoverer in existence, and the price paid for it was over $10,000, on account of the desire of another Chicago millionaire and art collector to possess it. The painting was originally in the possession of Margaret, Queen of the Netherlands, for whom it was painted from two miniatures done for the royal family of Spain. It was this portrait that Washington Irving, after a two years' search in Europe, used in his book as the best likeness of Columbus. The frame is a masterpiece of the carver's and gilder's art. It is surmounted by the coat of arms and quarterings of Columbus.

25 CTS. PISO'S CURE FOR CURES WHERE ALL ELSE FAILS. Best Cough Syrup. Tastes good. Use in time. Sold by druggists. CONSUMPTION 25 CTS.

Armour's

Extract of BEEF.

The best and most economical "Stock" for Soups, Etc.

One pound equals forty-five pounds of prime lean Beef.

Send to us for our book of receipts, showing use of ARMOUR'S EXTRACT in Soups and Sauces.

ARMOUR & CO., Chicago.

WATCHES.

EVERY one wants a watch, and naturally a good watch that keeps accurate time, presents a handsome appearance, and is inexpensive. If such a watch can be found of American manufacture, it is an additional appeal to our patriotism. Just such a watch as this ideal THE ANALYST PUBLISHING COMPANY is enabled to offer as a Premium to its readers. Having some large advertising contracts we have been enabled to procure the movements of the manufacture of the best known American watch factories, namely, the Waltham, Elgin, Hampden and Illinois Watch Companies. These movements are adapted for both ladies' and gentlemen's watches, and are warranted by the makers. These movements have seven jewels, patent lever movement, chronometer balance, patent safety pinion, sunk hard-enameled dial, straight line visible palette, stem winders, hand set; in fact, contain all the latest improvements and can be readily cleaned or repaired by any ordinary good watchmaker. They can be regulated to run as close as any movement.

It is needless to say that to case these movements in solid gold cases would make them too expensive, yet they are cased in what are known as gold filled or stiffened "Ladd" cases, and are warranted to be 14 karat gold, made from two sheets of 14 karat gold overlaying fine composition metal, with regular jointed caps, covers and bezels, and to wear at least five years. They are not plated, nor rolled gold, but actual 14 karat gold cases, thin of course, but stiffened and strengthened by being filled with this fine composition metal. They are finished in the same manner, engine turned and engraved as solid gold watches, and wear and look just the same. No one but an expert can tell them from a solid gold watch. These watches are made both open face and hunting case style, in gentlemen's or ladies' sizes. For gentlemen we recommend plain engine-turned cases; for ladies, a handsomely engraved case.

How to Obtain One of these Watches.

These watches are not to be purchased from us at any price. Send us a club of 25 subscribers to the AMERICAN ANALYST, and $25, the regular subscription price, and one of these watches (your choice of style and size) will be immediately forwarded, post-paid and registered, to your address. You need not wait until you have your 25 subscribers all together, but forward them as you get them and they will be credited to you, and when the number is complete the watch will be sent. A subscription for two or three years will be counted as two or three subscribers.

As these watches are retailed by jewelers at not less than $25, it will be seen that we are offering a real premium with the sole object of increasing our circulation, and that by taking advantage of our offer any one can obtain a good, reliable and handsome watch without cost. As the number of these watches at this price is limited, it is advisable to take steps at once to procure a bargain.

THE ANALYST PUBLISHING CO., 19 PARK PLACE, NEW YORK.

BICYCLES

GIVEN AWAY TO BOYS AND GIRLS!

AN OPPORTUNITY OPEN TO ALL.

The Analyst Publishing Company being desirous of largely increasing their subscription list, will furnish every one with a beautiful Safety Bicycle, ABSOLUTELY FREE, in return for a few hours' canvassing.

To every boy and girl who secures 75 subscribers for the American Analyst at $75, we will give a splendid

$40.00

NONPAREIL

SAFETY BICYCLE.

These bicycles are adapted in size to boys, but are strong enough to carry a man. A boy's bicycle should be a strong one. They are manufactured by the OVERMAN WHEEL CO., the makers of the celebrated VICTOR Bicycle, and have the full guarantee of the makers.

The following is a brief description of the NONPAREIL SAFETY; 26-inch wheels; ball bearing all around, including pedals; solid crescent rims; double tangent spokes; three-fourths inch tires; cranks, three throw, 4¼ to 5¾ inches; guards to both wheels; tool-bag, oiler and wrench. Finished in bright enamel, all exposed metal heavy nickel-plate on copper.

In selecting these machines as a premium, we have disregarded cheapness and selected a Bicycle which is serviceable, and the makers of which have an established reputation for building the best Bicycle that money, machinery and brains can produce. We are actually furnishing the Bicycles and Papers at less than cost, but hope by stimulating active and successful canvassing, and thus enlarging our subscription lists, to make an eventual profit. We positively guarantee these bicycles to be just as here represented. They will be shipped by express f. o. b. in New York.

Subscription orders must be made out plainly and legibly, and sent as fast as secured, addressed to

THE ANALYST PUBLISHING CO., 19 Park Place, New York.

TABASCO PEPPER SAUCE,

OR LIQUID PEPPER.

Is simply the Pulp of the Ripe Pepper Extracted by Pressure.

The seed of this Pepper was obtained from Central America, and by careful cultivation in Louisiana for many years has been so improved in strength, flavor and aroma, as to have become a new variety of Red Pepper, superior to all others. The pulp is so handled as to retain all the flavor, strength, aroma and color of the ripe fruit, and to keep unimpaired in any climate. It excites the appetite, promotes digestion, and is pronounced by connoisseurs to be the finest condiment in the world. For medicinal purposes it recommends itself by its purity, strength and diffusible form.

Manufactured by E. McILHENNY'S SON,

NEW IBERIA, LA.

JOHN DUNCAN'S SONS. NEW YORK.

DO YOU KNOW THE **DANGER** OF USING SOAP?

IF YOU ARE GOING TO THE COUNTRY, DO NOT FAIL TO READ THE FOLLOWING.

We do not mean soap made from proper material; and when we tell you that about ninety-nine per cent. of Toilet Soap is made from refuse fats gathered from tenement houses, hospitals, butcher shops, and from cattle dying of disease or during transportation, you will, we believe stop and think. Putrefactive changes have taken place in most of this material, as it is mixed with lean meat, blood, bones, sinews, etc. There is at least *one* soap that is made wholly from vegetable material—OLIVE and PALM OILS—and that is

VELVET SKIN SOAP.

It will keep the skin soft and in a healthy condition, as no animal fats are used in its manufacture.

Nothing in one's personal outfit is quite so satisfactory as a thoroughly reliable Toilet Soap.

We are confident that a trial of this article will insure its continued use. If the dealer does not keep it, do not take any other, but require him to order it for you, which he can do readily. **Otherwise, send to us direct.**

MANUFACTURED BY

GRAND PREMIUM OFFER!

A SET OF THE

WORKS OF CHARLES DICKENS,

In Twelve Large Volumes,

Which we Offer with a Year's Subscription to this Paper for a Trifle More than Our Regular Subscription Price.

CHARLES DICKENS.

Wishing to largely increase the circulation of this paper during the next six months, we have made arrangements with a New York publishing house whereby we are enabled to offer as a premium to our subscribers a **Set of the Works of Charles Dickens,** in **Twelve Large and Handsome Volumes,** with a year's subscription to this paper, for a trifle more than our regular subscription price. Our great offer to subscribers eclipses any ever heretofore made. Charles Dickens was the greatest novelist who ever lived. No author before or since his time has won the fame that he achieved, and his works are even more popular to-day than during his lifetime. They abound in wit, humor, pathos, masterly delineation of character, vivid descriptions of places and incidents, thrilling and skillfully wrought plots. Each book is intensely interesting. No home should be without a set of these great and remarkable works. Not to have read them is to be far behind the age in which we live. The set of Dickens' works which we offer as a premium to our subscribers is handsomely printed from entirely new plates, with new type. The twelve volumes contain the following world-famous works, each one of which is published *complete, unchanged, and absolutely unabridged:*

DAVID COPPERFIELD,
MARTIN CHUZZLEWIT,
NICHOLAS NICKELBY,
DOMBEY AND SON,
BLEAK HOUSE,
LITTLE DORRIT,
OUR MUTUAL FRIEND,
PICKWICK PAPERS,
BARNABY RUDGE AND CHRISTMAS STORIES,
OLIVER TWIST AND GREAT EXPECTATIONS,
THE OLD CURIOSITY SHOP AND THE UNCOMMERCIAL TRAVELER,
A TALE OF TWO CITIES, HARD TIMES AND THE MYSTERY OF EDWIN DROOD.

The above are without question the most famous novels that were ever written. For a quarter of a century they have been celebrated in every nook and corner of the civilized world. Yet there are thousands of homes in America not yet supplied with a set of Dickens, the usual high cost of the books preventing people in moderate circumstances from enjoying this luxury. But now, owing to the use of modern improved printing, folding and stitching machinery, the extremely low price of white paper, and the great competition in the book trade, we are enabled to offer to our subscribers and readers a set of Dickens' works at a price which all can afford to pay. Every home in the land may now be supplied with a set of the great author's works.

OUR GREAT OFFER

TO SUBSCRIBERS

TO THE

AMERICAN ANALYST.

We will send the **ENTIRE SET OF DICKENS' WORKS,** *in* **TWELVE VOLUMES,** *as here described, all postage prepaid by ourselves, also* **THE AMERICAN ANALYST** *for* **ONE YEAR,** *upon receipt of* **$1.50,** *which is only* **50** *cents more than the regular subscription price of this paper.* Our readers, therefore, practically get a set of Dickens' works in twelve volumes for only **50** cents. This is the grandest premium ever offered. Up to this time a set of Dickens' works has usually been $10.00 or more. Tell all your friends that they can get a set of Dickens' works in twelve volumes, with a year's subscription to **THE AMERICAN ANALYST** for only **$1.50.** Subscribe now and get this great premium. If your subscription has not yet expired, it will make no difference, for it will be extended one year from date of expiration. We will also give a set of Dickens', as above, free and post-paid, to any one sending us a club of three yearly subscribers.

THE KILL OR CURE SYSTEM.

It seems a pity that a discovery bidding fair to benefit the world should be prematurely forced into public attention, as was the case with that of Professor Koch, of Berlin. What may be the ultimate outcome of the famous "lymph" it would be vain to predict, though it undoubtedly will result in some marked advancement in the curative treatment of phthisis. But the popular disfavor with which its claims are considered to-day is in marked contrast to the enthusiasm that the mere sounding of its name six months ago excited. The trouble was, the public was let into the secret before the discoverer had fairly begun the experiments that were to determine its value. The same thing has happened before. The best plan is to suspend opinion in the case of new systems of treatment until they have been tested by time and experience. Such, for example, would be the action we should especially recommend in regard to a new method which we find mentioned by the Chicago *Herald*, and which we venture to designate as the "Break-neck Cure." It appears from our contemporary that a cure has been discovered at Reading, Pa., for epilepsy, that seems to be effective, as it can be relied upon either to kill or to cure. An eight-year-old boy who had been afflicted with epilepsy for four years, during one of his paroxysms fell from a third story window to the pavement. His mother rushed out to pick him up dead, but found that he had picked himself up and gone off. He was badly bruised, but was sent to the hospital, where he was treated for his injuries and has recently been dismissed sound in body and mind, and with no symptoms of epilepsy since his fall. The remedy is a heroic one, and the story bears some resemblance to the one related by Charles Reade in one of his stories where reason returns to the hero after an unexpected plunge in the sea. The great difficulty about such remedies is that they must be the result of accident. Throwing one's self in the sea or from a third story window will not serve the purpose. A "happy accident" occasionally does more for a patient than all the disciples of Galen can do. But such accidents cannot be counted on in the materia medica, and have, as a rule, too much danger and responsibility attending them to encourage the friends of a patient in arranging for accidents for him.

CALIFORNIA PHENOMENA.

The remarkable overflowing of the Colorado River into the great Colorado desert in San Diego County, Cal., described in the AMERICAN ANALYST of July 9, has had a stupendous sequel in the shape of a mighty earthquake, accompanied by a tidal wave in the Gulf of California. On July 30 an earthquake is reported to have completely changed the course of the Colorado River, which left its old bed and poured its waters through a crevasse a thousand feet in length. Another effect of the convulsion was the revived activity of the volcanos in that region, which in turn produced a great tidal wave, estimated by the few terrified persons who saw it as having mounted to a height of one hundred feet at the head of the Gulf of California. A newspaper correspondent at Yuma furnishes some interesting details of the occurrence. During the earlier excitement above referred to at Salton Lake, at least one half of the Colorado River, which even at this season of the year is a stream six hundred feet wide and twenty feet deep, made its way into the desert a few miles from Yuma, and eventually flowed north and into the Salton basin. The thirsty desert failed to drink up all the river, and it seemed as though mighty forces came in alliance to wipe this great stream off the map. Early on the morning of July 30 premonitory rumblings gave notice of a coming storm. The earth trembled under foot; then came a mighty crash, as though subterranean artillery by thousands of pieces had been discharged. The people rushed from their houses at the first signal, to be thrown flat on their faces. The adobe houses just vacated went to pieces, the air was filled with clouds of dust, and for a few seconds the day of judgment seemed to reign. The terrified people cautiously rose to their feet and moved about, horrified to find that what before had been solid ground yawned with cracks and crevices apparently without bottom. Hills had slid from their foundations and occupied new stations. The very river itself had disappeared. Where before flowed a shallow, sluggish stream of the color of ochre was now only a channel of mud. This did not, however, remain long, and the river gradually reappeared, but yet in diminished volume. The testimony of a hunting party that witnessed the appalling convulsion of nature near Lerdo, Mexico, gives a thrilling idea of the powerful forces underlying the crust of the earth we inhabit. Of a sudden the sky was darkened, and the waters of the river seemed to be climbing mountain high, as a great tidal wave from the Gulf of California came pushing, crowding, and boiling ahead with its wall of foam and fury. The frightened men, struggling for high ground, could see through the darkness the foam-flecked waters. Corrals, fences, and landing-places were washed away. The shaking of the ground increased, while the horrible crackling, grinding noise of rended rocky hills seemed to increase each moment. To add to the horror of the scene, a terrible thunder-storm arose, and the lightning flashed as it never flashed before in that country. In a little while the storm subsided, the gulf wave receded, and the party started back for Lerdo. But shortly a second shock, much stronger than the first, was experienced. The earth opened in many places, and the tremor threw the men down with much force, rendering them unconscious for some time. When about to resume their journey they found many places from four to seven feet wide and twenty to thirty feet long, and apparently fathomless, which had been opened in the earth by the second shock.

UNIVERSAL SPECULATIONS.

There is a brilliant contributor to the columns of the *Electrical Review* who, through mistaken modesty, perhaps, conceals his identity under the sobriquet of "The Prophet." Who he is we do not know, though his comprehensive mode of thought and daring speculative grasp bring to mind some corresponding characteristics of Nikola Tesla, of whose remarkable lecture on Electricity last May, before the Institute of Electrical Engineers, an abstract, necessarily too short, was published in the AMERICAN ANALYST of August 6. Our readers may remember our reference some months ago to a suggestion of "The Prophet" regarding a telescope in which the usual object glass should be replaced with a specially contrived electric field of large dimensions. The capacity of such an instrument, could it be constructed, would be enormous, and its revelations correspondingly extensive. "The secrets of the other

planets," as the writer declares, "would then be ours." In a subsequent paper the same ingenious scientist reverts to the electric field lens idea to maintain that it need not be restricted to telescopes. "The essential feature of a microscope is the eye-piece"—we presume he meant the "objective"—which, he continues:

"Should be a minute sphere of perfect glass. The grinding and polishing of such a small globule of glass as is required in a high power microscope is the only limiting factor in microscopy. It is conceivable that an electric field could be formed which would be as small as a mathematical point. What could we see with such a microscope? Fitz James O'Brien gives us, in his 'Diamond Lens,' a beautiful poetic vision of what his hero saw with a lens of immense power which he had constructed out of a large diamond and treated with an electric current. While it is not likely that a powerful electric lens would reveal to our astonished gaze visions of prismatic groves and the beautiful 'Animula' with whom O'Brien's hero fell in love and pined away because he could not speak to her, yet the scientific imagination goes on a flight which quite equals that of the poet."

And here the "scientific imagination" takes in fact a leap that condenses in a single short paragraph food for the mind to occupy itself with, to the exclusion of other concerns, for quite a period of time. We are led to infer that if the true poet must be inspired, the true scientist must be a poet. For our "Prophet" concludes his letter in the following words, which we commend to such of our readers as are familiar with John Fiske's "Unseen World." "This at once brings up the query: What is matter? We are told that matter is made up of molecules, and that the distances between molecules are immense compared with their size. If we could conceive of a being small enough to exist on a molecule and he should gaze off into space, the nearest molecules would appear to him at such distances as the stars do to us. The idea of a grain of sand containing worlds of its own is too stupendous even for a poet. Yet who can say that such is not the case. Then, to turn to the other extreme, suppose the earth to be an atom, our solar system and perhaps our universe forming a pebble on the shore of some vast ocean space!"

RAIN COMPELLERS.

DESERT LANDS TO BE REDEEMED BY THE AID OF HIGH EXPLOSIVES.

A Washington correspondent writes to the Philadelphia *Press*: Gen. R. G. Dyrenforth, of this city, who is to have charge of the experiments for the production of rain by artificial methods, leaves here in a day or two for the scene of his experiments. Just what spot will be selected is not yet determined, or if it is the precise locality is kept secret. There is no disposition to deprive the public of any information as to the manner of conducting the experiments, or as to the results, but Gen. Dyrenforth says frankly that he will have so much on his mind, and so much labor and careful calculation and study to be performed in this experiment, that he does not wish to be interrupted by inquirers or investigators during the progress of the work. "I intend that every fact shall be known," he said, "and in the most intelligent and useful form possible, but I want to make the experiments first, and to make them carefully. Then there will be time enough to tell the story of the work and the results, if there are any." "You do not speak in very positive terms as to results?" "Why should I? It is an experiment, pure and simple, one never tried before, and there are no data or even the most unimportant experience to guide us in forming an opinion as to what will be the result. I certainly hope that it may be a success, and the more I study the matter the more strongly I am impressed with the feeling that there may be a good foundation for the theory that concussions produce rain, whether they will do so under the unfavorable conditions which prevail in the regions where this sort of thing is most needed is, of course, quite another question. But so far as I am concerned, I intend that the test shall be as thorough and as intelligently made as possible under the circumstances." The history of this curious and important experiment is known to but few. Some years ago an Illinois engineer, Edward Powers by name, published a little book showing that many of the great battles of the world had been followed by rain, and arguing that it might be practical to produce rain by explosions of powder. He estimated, however, that the experiment would cost from $20,000 to $30,000, and his theory was not taken hold of. Senator Farwell, of Illinois, however, became much interested in the theory, and on talking with other members of Congress who had had war experience, found that they believed in the theory. He also found another supporter from another walk of life, and a very valuable contribution it was to the information on the subject. This supporter was no other than Senator Stanford, who said that his experience in building the Central Pacific road was in direct support of the theory. Much of this road was built through a section of country where rain seldom, if ever, fell; yet, soon after the work began in this rainless region, and the heavy blasting that was necessary to cut the way through the mountains of granite was under way, there were frequent, almost daily, rains, and this condition continued until the blasting ended and the road was built, when the rain ceased. So a clause was added to the appropriation bills in the two sessions of the last Congress, appropriating $9,000 for experiments to be conducted under the direction of the Department of Agriculture. In looking about for somebody to conduct the experiments, Assistant Secretary Willetts found that Gen. Dyrenforth, ex-Patent Commissioner, had given the matter some thought, largely through his acquaintance with Senator Farwell, and he was asked to take charge of the work. The field was an entirely new one. He began the study of the history of battles with reference to rainfalls, then the question of explosives. He soon conceived the idea that if it is concussion that acts upon the air to produce the result, it would be better that the concussion should be in the stratum of air where the rain is to be formed. How to get it there was the question. To send up captive balloons was easy, but to send them up loaded with dynamite or nitro-glycerine, and take the risk of some of them getting away unexploded, was too serious. Besides, the explosion of dynamite or nitro-glycerine produces too quick and sharp a sound. What he wanted was something like thunder, which will shake the atmosphere. He remembered that sharp claps of thunder in the midst of rain are often followed by a great increase in the rainfall. Being himself a graduate of the school of technology, he was perfectly familiar with the fact that a combination of hydrogen and oxygen gases is easily exploded. The happy thought suggested itself to his mind that these gases would be needed to carry up the balloons which were to transport the explosives, and the very article furnishing the motive power might itself be the explosive best fitted for the work. So he experimented, and exploded a few balloons near Washington with the most astounding results. This matter satisfactorily settled, he set about the practical preparations. He hunted up Prof. Carl E. Myers, the distinguished balloonist, at his New York home, and, finding him well posted on the production of hydrogen in quantities, directed him to utilize his experience in balloon construction and hydrogen making in aid of the project. He then devised a machine for the production of oxygen in large quantities in the field, and finding that it worked perfectly, sent forward a car loaded with the necessary material for the experiment, and is now to follow with a party of skilled assistants and begin the experiments. The party will consist of Gen. Dyrenforth as general director of the work; Prof. Myers and G. W. Casler, balloonists; Dr. Rosell, chemist; Paul A. Draper, electrician; George W. Curtis, meteorologist. A place will be selected where there is little if any rainfall at this season of the year, and near to a signal station, so that the benefit of the services and predictions of the observers may be had. The meteorologist and electrician will be provided with the most delicate instruments for testing the electrical conditions of the atmosphere. The experiments will begin in a small way, with the explosion of a single balloon, and observation as to the effect upon the amount of moisture and electricity in the atmosphere immediately surrounding. Experiments will also be made to discover whether the explosion of the balloons would be likely to cause the explosion of the dynamite or other explosives of that character which it is proposed to use simultaneously later on. Captive balloons will be sent up carrying observers to test the quantities of moisture and electricity at various heights of from 1,000 to 7,000 feet above the earth. These will be connected by telephone with the earth, so that observations may be taken simultaneously with delicate instruments at the earth and in the various strata of air at a distance of from 1,000 to 7,000 feet. If it is found that a stratum of air at a mile height has more moisture than near the surface, experiments will be made to see what the effect of explosions there will be, and whether the rain, if produced, will be able to fall through the dry air below it without being absorbed, and if it is so absorbed, whether it can be shaken out of the lower stratum of air that so absorbed it. Observations will meantime be taken both on the earth and in captive balloons as near to those exploded as it is safe for them to approach. When these preliminary experiments are satisfactorily made, the grand experiment will begin. A line of explosives will be placed in about the position that a line of battle is arranged, stretching about three miles in length and a half mile in width. There will be various kind of explosives. On the ground there will be a mortar for firing "rack-a-rock" powder and dynamite, so that the earth may do its part in conveying the sound and motion from the concussion, and that the smoke, which is supposed by some to have some bearing, may also be present. There will be large kites, from six to twelve feet high, which will be sent aloft bearing a bunch of explosives at their tails, and connected by a fine copper wire with a battery. In order to get the required height with these they will be "driven tandem," attaching the end of as much line as the first one will carry to the second kite and sending both on up, attaching the second to the third, and so on. This plan will also be pursued where necessary in getting balloons with wires attached to the necessary height. The mortars planted and the kites in air, the balloons will be sent up, at a distance say of 1,000 feet apart, and the racket will begin. It is the intention to keep up this din to the god of rain for two or three days, or perhaps longer, noting the atmospheric changes, both on earth or in the air at various heights, constantly as the "battle" goes on. These observations will be taken, and officially and scientifically noted, both as to atmospheric and electrical conditions. There is enough of the sound-producing material to hold about three of these "battles." The party will take 100 balloons, from 10 to 20 feet in diameter, and capable of holding from 500 to 5,000 cubic feet of gas; hundreds of kites, from 6 to 12 feet high; miles of copper wire, quantities of nitro-glycerine and dynamite and powder; batteries for generating electricity, and machinery for generating hydrogen and oxygen. These machines devised for generating oxygen will make more oxygen in an hour than was ever made by any machine before in a day. They look like sheet-iron stoves with steel cylinders stuck in at the top and connected by a rubber hose with the line of hose that leads to the cellar. The tubes are filled with potassium chlorate and black oxide of manganese, and by heat from gasoline burners in the stove the gas is generated. The experiment is not in any way a "crankism." Congress directed that it be done, and it is said that a hundred members of that body believe in the

theory underlying it. Assistant Secretary Willetts, who was directed to carry it out, himself a scholarly man, found the best suited men he could for the immediate work, and he is taking hold of it intelligently, willing to accept whatever result may follow, but determined to omit no effort for success. Whatever the immediate result to science and to all interested, the full benefit of intelligent, careful observation will be had at every step in an experiment involving great possibilities, and whose success would make the desert to blossom as the rose, and open homes for millions of people where now life is impossible.

A POND'S REVELATIONS.

A WORLD FILLED WITH COUNTLESS KINDS OF BEINGS.

To the naturalist a slimy, stagnant pool in the woods, filled with nastiness and disgusting of smell, is a world replete with fascinating interest, the home of countless kinds of beings, strange and wonderful. To begin with, the water teems with myriads of the very minute animals called infusoria, creatures of varied and curious shapes, some naked and others protected by limy shells. Of these there are hundreds of sorts, resembling, when seen under the microscope, coins, boats, stars, trumpets, pitchers, and wheels. Many appear also in the forms of fruits, necklaces, flasks, funnels, fans, and so forth, ad infinitum. A very common one is called the "flower cup," being in the likeness of a crystal vase containing what looks like the blossom of a plant. So small is this specimen that 13,000,000 of them may be comprised within a single drop of water. These little beings have eyes, muscular structure, and even nervous systems of their own, as it is believed. They move swiftly in pursuit of prey by means of oars, and a few of them actually have claws with which to grasp. Some of them lay eggs, others bring forth their young alive, while others still are propagated by division, each one separating into two. A few species are big enough to be seen with the naked eye, and one such, called the Stentor because of its trumpet shape, is particularly ferocious, devouring great quantities of its smaller cousins. More interesting even than these are the swarms of minute diatoms—creatures of a vegetable nature, which are chiefly remarkable for the elaborate beauty of their shells. The latter are bivalvular, like those of a mussel. Some are like little boxes, exquisitely made; others resemble boats, hearts, dominoes, etc. There is one sort that has been called the "Shield of Achilles," because each half of its disk-shaped shell is cut in concentric circles, with a complicated tracery of designs. In many varieties the valves seem ornamented with so fine a lace work that to distinguish the patterns is considered the best possible test of the power of a microscope. Inasmuch as the biggest ones can hardly be seen with the unaided eye, one kind is separated from another for purposes of study by pouring the water containing them from one breaker into another, then into still another, and so on, each time allowing a brief time for them to settle partly. Those which are heavier reach the bottom of the vessels before the lighter sorts, and thus the different species are separated by weight for mounting finally upon glass object slides. To obtain the clean shells they are boiled in nitric acid and treated with caustic potash. There are plenty of creatures in the stagnant pool however, which may be seen without the aid of microscope. For example, there are polyps, animals about a quarter of an inch in length, which look like little tubes of jelly as thick as a bristle, with thread-like arms for seizing their prey. They are incredibly fierce, and naturalists believe that they possess the power to paralyze their victims by electric shocks in the manner of the torpedo fish and the electric eel. In this way only can the fact be explained that their slender tentacles are able to secure game comparatively so large and powerful. A specimen has been seen to grasp two large worms at the same time, and yet the latter, though struggling desperately for their lives, were unable to break away, and in a moment lost all power of motion. Now and then a swelling appears on one part or another of the polyp's body, and from each such protuberance finally appears a young polyp, which separates from its parents when it is sufficiently grown to take care of itself. If any portion of the animal is cut off it soon grows again. One that is chopped in two quickly becomes two perfect individuals. Furthermore, if turned inside out like a glove it accommodates itself to the new arrangement, the original outer skin performing, as a lining of the interior, the office of digestion. Among the most curious of the pool's inhabitants are the larvæ of various insects. Most conspicuous of these is the mosquito in its aquatic stage, when it is fed upon voraciously by the larva of the dragon fly, or darning needle, as it is often called, which resembles a fierce-looking worm. It is well known that the dragon fly is an equally dangerous foe to the mosquito when both have acquired wings. To illustrate this the writer will venture to tell a true mosquito story. On Cape Cod there is a great fresh-water pond, formed originally by an advance of the ocean, which gave such alarm a few years ago that a dyke was constructed along the shore line to keep back the waves. Inside the dyke the water, which had formed a sort of lake, gradually became fresh, coarse grass grew thickly in it, and it was transformed into an ideal breeding place for mosquitoes. As the latter rise in swarms from this morass, myriads of dragon flies hover to leeward in wait to capture their favorite prey. So enormous are the numbers thus eaten that on a summer's day, in the wind ripples made in the sand, one may easily sweep together within a few minutes more than a bushel of dead mosquitoes, only the shells of the insect being left by the dragon flies after sucking out the juices. Among the most numerous of the visible occupants of the stagnant pool are the larvæ of the May fly, which in seasons unusually favorable to their production sometimes visit towns in such numbers, being blown before the wind, as to litter the streets, many cart loads of them being on occasion swept up and carried to the dumps. Another remarkable insect found in the slimy water is called the "monoculus," and is covered with a delicate shell marked with so fine a network as to present the appearance of mosaic. This valve is perfectly transparent, consisting of a single piece without hinge or joint, but sufficiently elastic to permit the animal to open it at pleasure. It affords protection not only to its occupant but also to the young of the latter, which swim into it when danger threatens, the shell opening for their reception and closing as soon as they have entered. Mention should not be neglected of many kinds of water beetles, which are very voracious, and are armed with strong claws for grasping their prey and tearing it to pieces. If a few are put in the same vessel together, they will fight with the utmost ferocity. At the bottom, among the weeds and leaves, are found certain caterpillar-like animals, which are nearly transparent. This species is called the "lurco," or "glutton," its entire body being occupied by a series of stomachs. Ever so many kinds of aquatic worms find their home in the pool, being often so numerous in the shallows as to color the mud red. Leeches are plentiful in such places, as every boy knows. There are several species of crustaceans, most conspicuous among them being the "cyclops," so called because it has but one eye, of a crimson hue, with two pairs of horns on each side of it. The body of this "water-flea," as it is sometimes designated, is covered with plates of armor, the shell-like material being usually transparent, like crystal, though sometimes adorned with beautiful tints. Turtles, also there are of certain varieties; likewise newts, polliwogs, frogs, snakes of more or less aquatic habits, and plenty of other animals too well known to speak of here. Not least important, in point of numbers or otherwise, of the organisms inhabiting the slimy, stagnant pool are bacteria of endless varieties. Most of them are harmless, but some are the germs of frightful diseases. To prove it, let any one try to drink the water, in which lurk malaria, typhoid fever, bowel disorders, and other horrors besides.

INITIATED.—"We have home-made pie," said the waiter lady in the Woman's Exchange. "Excuse me," said the pallid young man as he reached for his hat and started for the door, "I was looking for bakers' pie. I was married only last month."

OLD PATENT.—The earliest Connecticut patent found on record was granted in October, 1717, to Edward Hinman, of Stratford, for the exclusive right and liberty of making molasses from the stalks of Indian corn, in Fairfield County, for ten years, which grant ended with the words: "Always provided the said Hinman make as good molasses, and make it as cheap, as comes from the West Indies."

POISONED FISH.—The *Lancet* contains a warning against the use of iced fish. Ice spoils the freshness, firmness, and flavor of fish by rendering it, prior to putrefaction, insipid, soft, and flabby. When fish is preserved on ice, it appears that the ice only favors putrefaction by furnishing a constant supply of moisture, carrying with it the putrefactive bacteria derived from its unclean surroundings, so that this iced fish remains covered with fresh solutions of filth, pregnant with putrefactive bacteria. On the other hand, keeping fish dry and cold can in no way favor putrefaction.

BROTHER JONATHAN.—In Lebanon, Conn., on June 15, the Connecticut Historical Society, assisted by the Connecticut branches of the National Society of the Sons of the Revolution, took formal possession, with imposing exercises, of a most interesting and valuable Revolutionary relic building that was the office and the executive seat of Gov. Jonathan Trumbull, or "Brother Jonathan," as he was called, throughout the whole period of that war, and which has been donated to the State. The town was filled with visitors. The leading addresses were made in the forenoon by United States Senator J. R. Hawley, and in the afternoon by the Rev. Leonard W. Bacon, D. D.

FRENCH CANDY.—The very best "French" candy is now made in this country, but a very small quantity being imported. The tariff is 35 per cent. of the actual value, and that makes the imported article too expensive to have any chance against home manufactured goods. The secrets of the trade are, of course, numerous, and several of them have been brought to this country by emigrants and others. It is doubtful whether any candy now comes from France to the trade, though no doubt a good deal is brought by tourists and visitors. In the same way, "French" candy in the United States is often taken to Paris, while our best caramels have quite a large sale in all European capitals. The foreign makers cannot get such maple sugar as we use, and hence their inability to supply the home demand. In crystallized fruits France still holds front rank, the neat way in which their goods are finished and packed helping to maintain their popularity.—*St. Louis Globe-Democrat.*

LONDON'S SOOT AND FOGS.—The amount of carbonaceous and other particles deposited upon glass houses is a good indication of what the London atmosphere contains, and in many places it is only possible to procure a due admission of light to the plants by frequently washing the glass roofs. At one establishment last week two tanks constructed to collect the rain from a house completed a few years since, were cleared out, and no less than ten barrow-loads of sooty matter were removed, all of which must have been conveyed into the tanks from the glass. One scientific gentleman has been engaged in computing the amount of soot deposited from London air, and arrived at the following conclusions: He collected the smoke deposited on a patch of snow in Canonbury one square link, about 8 inches in extent, and obtained from it two grains of soot. As London covers 110 square miles, this would give us for the whole area 1,000 tons. As the quantity measured fell in ten days, a month's allowance would need 1,000 horses to cart it off, and these stretched in a line would extend four miles. Hence London's black fog.—*Pharmaceutical Record.*

ELECTRICAL PROGRESS.

WHAT ELECTRICITY IS EXPECTED TO DO AT THE COLUMBIAN EXPOSITION.

According to the Chicago *Herald* electricity now manœvers a bridge over the Chicago River. Within a short time it will probably supersede steam or hand power at all of them. There are two suburban electric surface railways, and authority for another has just been issued. The operation department of the World's Fair has just announced that the electric power plant for its use will be the greatest the world has yet seen. It will be the equivalent of 24,000 horse-power. At Philadelphia one Corliss engine of 1,456 horse-power did all the work. At the last Paris exposition 6,000 horse-power was required. Three electric cranes will run lengthwise in the Chicago machinery hall. Each will have a speed of 400 feet per minute, and a carrying capacity of 20 tons. They will be used for installation and removal of exhibits, for all motive power functions during the fair, except where exhibitors have special reasons for employing another, and will transport passengers from place to place within the inclosure. Electric energy plant in the machinery annex will require engines of 16,000 horse-power. The current will go directly through the entire grounds by wires from the plant. It will also light the grounds and buildings. Popularization of electricity has been progressing at accelerated rate. It will probably surprise many people to know that there are now in the United States in actual operation 307 electric street railways. They are distributed over forty states and territories. It is curious to note that while slow-moving Canada has only one, the young State of Washington has thirteen. It is observable, also, that they are most numerous in northern States, like New York, Pennsylvania, Massachusetts, Ohio, Illinois, which has twenty-two, and least numerous in southern states. Alabama and Arkansas have one each, Delaware one, Kentucky and Louisiana one each. In the far West the new force is invading mines. The proposal that by means of electricity the waters of Niagara Falls shall be made to run machinery in Chicago during the Fair seems less astonishing in view of the fact that water miles distant from mining camps is actually running their mills by means of wires. In one case a mine 1,500 feet above the s a, in a locality where fuel is scarce and no railway within fifteen miles, the problem of power was easily solved by electricity tapping a mountain stream with a circuit more than three miles in length. Niagara running lathes in the Columbian Exposition in 1893 will be less wonderful in this age than predictions of the applicability of the electric fluid for industrial use were a hundred years ago. The popularizing of the still only dimly understood force has progressed in many directions. It has transformed journalism from a mail bag into a flash-light. It has made mirrors of continents, so that they are rapidly becoming reflectors of each other. It has penetrated mountains and descended into the sea. It is to scour the heavens with telescopes, and it will probably furnish before long entirely new light to physical science by its already demonstrated power to weld metals. It has been plating metals for some time; now it is going to forge them as well. It ventilates, cools, or heats houses. In the Chicago *Herald* office it runs a fan by which a constant draft of fresh air is kept in motion. In a placer gold bed it trickles a stream of water that washes the ore and sends it out ready for the mint. It transmits messages along running trains, and will in a short time prevent collisions on land or water by giving automatic signals of proximity and speed. For its own propagation it has invaded other fields to secure new materials, and to compel invention of novel processes. It has introduced new chemistry and mechanics into pottery for the production of porcelain insulators. It has caused the manufacture of a substitute for india rubber better suited for the same purpose. It has encouraged successful experiments in metals for transmitters and joints. It has even entered silk manufacture, and led to the design of new qualities adapted for its needs. It is coloring fountains in many great cities and running blast furnaces. It will doubtless become the automatic mover of railway switches, and will in time notify the approach of earthquakes and cyclones. The electrical exhibition now in progress at Frankfort-on-the-Main, which our Fair Commissioners are visiting, shows boats run by electricity on the river, a waterfall made a prismatic wonder by electricity, a telescope with electric searchlight. Music will be transmitted by electricity, and at the World's Fair we will have fireworks by electricity surpassing the weirdest and most beautiful dreams that have flitted across the imagination of man. It has apparently solved the problem of subterranean rapid transit. The Greathead Underground Electric Railway of London, running since November last, has been free from smoke, damp and bad air, partly on account of the new method of treating the tunnel sides with iron tubing, tarred rope and cement, thus insuring against gases and water, and partly because of the cleanliness of the motive power. The rate of transit is from twenty-two to twenty-five miles an hour, or twice as fast as the average speed on the New York elevated roads. The process of tunneling, it is claimed, also prevents excavations from affecting foundations of buildings. From whatever side we look at it, the popularization of electricity is speeding in all directions. The World's Fair in 1893 will be astounding in manifold manifestations of its uses.

BUDDHISM.

THE CREED OF THE GREAT CINGALESE BONZE.

In a paper written for *La Lecture*, of Paris, M. Robert de Bonnieres says: "Not every one is aware that of the thirteen hundred million inhahitants of the earth five hundred millions are Buddhists. If the question as to what should be the religion of the world were submitted to universal suffrage, the Buddhist religion, or rather that philosophical morality, would have the majority. Having a good reason for visiting in Ceylon the High Priest of the Church of the South, I did not fail to call on him. The great Bonze lives some miles from Colombo, the principal town of Ceylon, in the village of Maligakanda, where is his seminary. This is a large inclosure planted with cocoa-trees, mango-trees and teaks, among which are scattered some very simple square buildings, with overhanging roof, supported by wooden pillars. His head shaved, his feet encased in leather sandals, dressed in a yellow toga which left the right arm and shoulder bare, Sumangala was seated under a shed. Surrounded by young priests dressed in the same fashion as himself, he was giving them a lesson. They spelt together some texts in Pali, engraved with a bodkin on resinous palm-leaves; when the text was in verse they sang it in chorus, in the tone of our singers at vespers. When the lesson was finished Sumangala rose and conducted us under the veranda of his little lodging, passing on the way beneath an arbor of pink begonias. He was a small, plump man, with a brown skin, active, and benevolent looking. His eyes were black, soft and piercing, incessantly moving. The Cingalese interpreter brought a large copper vase, which served as a spitbox. The teeth and mouth of the high priest were red with betel and bloody saliva. Betel leaf with a Buddhist priest takes the place which snuff occupies with many of our country curates in France. Sumangala was born at Sipkaduva, near Point de Galle, on February 22, 1828. He learned the Cingalese alphabet at home, and acquired a thorough knowledge of the sacred languages in the Buddhist temple. He was a seminarist at twelve years of age, a priest at twenty-one. His family was rich. His father was in the judicial department of the English civil service; his brother was a professor in the Academy at Ceylon. At first priest at Point de Galle, then High Priest at Adam's Peak, my host came to Colombo in 1872. As the priests take the name of the village where they are born, he is called the Sipkaduva-Sumangala. The great Bonze began by telling me that I must not confound the Church of the North, which is established in Thibet, China and Japan, with the Church of the South, to which belong Ceylon, Burmah, the Kingdom of Siam, and Cambodia. For the Church of the South, of which he is one of the chiefs, he claimed the "purity" of the true teaching of Buddha, "who was the wisest of mankind." He proceeded to enlighten me as to some points of usage and doctrine. A Buddhist priest must devote his time to teaching and meditation. He rises at five o'clock in the morning, and takes a slight repast at six o'clock to appease his hunger until his principal meal, which is at eleven. During the rest of the day he is forbidden to eat, but not to drink; he is permitted to drink only tea or orange juice. If priests eat in the evening, their minds become heavy and lazy, and they are not able to teach as well. Buddhist priests and their followers are not allowed to kill animals. At this time, however, the question is discussed as to whether they may eat the meat of animals killed by other hands than their own. Perhaps a council will meet to settle the question. A council is called only to decide whether the sacred books have been altered, and to try a bad priest. A priest is deposed only for having committed one of the four great mortal sins, which are: An illegitimate union, theft, assassination, and the great lie. The great lie is saying one is *arrahat;* that is, that one is omniscient and is Buddha when he is not. Like the mendicant orders of the Middle Ages, Buddhist priests can eat naught but what is given them; they have no kitchen or means of cooking of their own. Their rules are more severe than those of the Benedictines; they live on the charity of the faithful alone, and are not allowed to make money out of anything. The house in which Sumangala resides was given him by subscription. In Ceylon there is neither government allowance nor funds for religious purposes. Buddist priests must have nothing to do with women, and cannot even give them their hand, under penalty of being suspended from their functions for several days and of submitting to expiatory prayers. Sumangala then passed to a summary explanation of doctrine. To facilitate these explanations he caused to be brought a Buddhist catechism in English, and we read together its questions and answers. What is a Buddhist? He is one who professes to be a follower of Our Lord Buddha. Was Buddha a God? No. Was He a man? In form He was a man; but internally He was not like other men; that is, in mental and moral order He surpassed all the men of His time and all other times. Was Buddha His name? No; it is the name of a state of mind. Its significance? Illuminated; or He who has perfect wisdom. Did Buddha discover the cause of human misery? At last He discovered it. As the light of the rising sun scatters the shades of night and reveals everything to view, so the light of knowledge rose in His mind, and He saw clearly the causes of human suffering and the means of escaping them. Did He have to make great efforts to attain this knowledge? Yes; He had to conquer all the defects, the desires, and the appetites which deprive us of the sight of the truth? What is the light which can disperse our ignorance and drive away all troubles? The knowledge of the Four Noble Truths, as Buddha calls them. What are those truths? First, that misery always accompanies existence; second, that all modes of existence result from passion or desire; third, that there is no escape from existence except by destruction of desire; fourth, the means of obtaining the destruction of desire. When we are in possession of the four Noble Truths, at what do we arrive? At Nirvana. What is Nirvana? The state of perfect repose, the absence

of desire, of illusion, of pain, the complete annulment of everything which constitutes physical man. Before attaining Nirvana, man can be incessantly born again; when he has attained it he cannot be born again. This morality, which sets up nothingness as the supreme end of life, and makes perfection itself consist of conscious stupidity, is the height of pessimism. Yet what renders this philosophy supportable and even touching is the profound reflection it gives to the study of man, and the pity filled with goodness which the sight of men's miseries causes. In taking leave of the great Bonze, I asked him what had been during his life his joys, and his sorrows? He answered, good humoredly, "My happiness has consisted in knowing Buddha more and more; I have had no sorrow."

APPLIED SCIENCE.

THE GERMAN SYSTEM OF ALLYING ACQUISITION AND INVENTION.

In the *Popular Science Monthly* for August Mr. F. W. Clarke says: During this century nine-tenths of the great discoveries have been made by men with institutions back of them, through the aid of which the work was rendered possible. Wealth, scholarship, ability, and the spirit of research, too, seldom go together; and happy is the man in whom all these conditions are fortunately united. The truth of my last statement may be verified by a reference to the files of those standard scientific journals in which original researches are recorded, or by scrutinizing in detail the history of any great discovery. In either case, whether we consider this country or Europe, the university work will be found to predominate overwhelmingly, and for obvious reasons. Every true university is something more than the distributor of knowledge. It is a producer of knowledge also; and in Germany, where the university system is most fully developed, the two functions are equally recognized. A German student, aspiring to academic honors, must do original work, and the professors' chairs are always filled from among the men who have most distinguished themselves as investigators. A chemist who has done nothing for pure science could hardly be recognized in Germany. Not one of the higher professional positions would be within his reach. Erudition alone, unsustained by evidence of creative ability, would do little for his advancement. In consequence of this policy, Germany now leads the scientific world, and in consequence of that leadership a certain industrial supremacy is fast becoming hers. One example will serve to illustrate the tendency to which I refer. The aniline dyes were discovered by Perkin in England about thirty-five years ago, and in that country the manufacture began. To-day, through the researches of German universities, Germany is the centre of the coal tar industry, and England has only a subordinate rank. Until recently the English universities have slighted experimental science, and English manufacturers are paying for the neglect. One German firm alone, producers of coal tar colors, employs over 1,400 workmen; but with them there are about fifty scientific chemists, every one a man trained in pure research, the product of the university system. These men are engaged to make investigations, to improve processes, to discover new compounds of value, and, in short, to use the most vigorous methods of science for the upbuilding of industry. The German manufacturer does not employ a chemist who has only learned by rote the wisdom gained by others. He does not ask to be told that which he already knows. He seeks rather to push forward into new fields, to excel his competitors more by intelligence than by brute force, and to gain a growing supremacy in preference to a mere victory for the moment. This practical policy, the outgrowth of intellectual culture, has made Germany a dangerous rival to all other countries in those departments of industry which rest upon scientific foundations. Applied science cannot exist until there is the science to apply; and where the latter is most favored, the industrial development is sure to be the most perfect. This lesson is one which the United States must learn more thoroughly than heretofore, if it hopes to hold its own in the front rank of manufacturing nations. In a few of our universities the truth is already realized; but in too many American schools the so-called "practical" view prevails. Under the latter, teaching becomes routine, and the student, while learning elaborately that which is known, is not taught how to discover. He has little or no training in the art of solving unsolved problems, and that art is the mainspring of modern industrial growth. A teacher of science ought also to be an investigator, were it only for the inspiration that his example might give to the pupils in his charge. To impart knowledge is a good thing, but to reveal the sources of knowledge is better, and in that revelation is found the educational value of research regarded as a part of the teacher's essential duty.

DOMESTIC DIETETICS.

SPECIALLY PREPARED, FROM PRACTICAL TESTS, FOR THE LADY READERS OF THE "AMERICAN ANALYST."

SEASONABLE FOOD.

August.

GAME AND POULTRY.—Pigeon, chicken, duck, woodcock.

MEAT.—Beef, lamb, mutton, ham, kidneys, liver, sausage, veal, venison.

FRUITS.—Cherries, raspberries, huckleberries, melons, gooseberries, blackberries, peaches, pears, tamarinds, bananas, pineapple, grapes, plums.

FISH.—Anchovy, bass, bluefish, blackfish, cod, eels, crabs, clams, flounders, halibut, herrings, lobster, mackerel, mussels, porgie, prawn, salmon, turtle, trout, sturgeon, whiting, weakfish, rockfish.

VEGETABLES. — Beans, beets, cucumbers, cabbage, carrots, cauliflower, corn, egg-plant, lettuce, onions, parsley, parsnips, potatoes, squash, shallots, spinach, turnips, radish, rhubarb, tomatoes.

PRACTICAL RECIPES.

CHICKEN SOUP.—Cut up all of a chicken with the exception of the breast, and break the bones, put the chicken in a soup pot with a pound of round steak cut into pieces. Cover with six quarts of water and cook until the chicken meat falls to pieces. Strain the soup, and to each quart add an ounce of rice, and simmer for three-quarters of an hour, then add the breast of the chicken, which has been cooked whole in the soup, cut into dice, a little minced parsley and seasonings of salt and pepper. The chicken soup meat may be used for souffle.

CHICKEN SOUFFLE.—Make a cream sauce as follows: Put a large table-spoonful of butter over the fire in a saucepan and when it is melted add a table-spoonful of flour, cook together for a few minutes then add a pint of hot milk. Stir well until the sauce is thick and smooth, then add to it while boiling two cupfuls finely chopped chicken, a teaspoonful of chopped parsley, a teaspoonful of onion juice, salt and pepper. Cook for two or three minutes only, then add the well beaten yolks of four eggs and set away to get quite cold. When cold add the whites of the four eggs beaten very stiff, and turn the whole into a buttered pudding dish. Bake for thirty minutes, then serve *at once* with cream sauce, in which there is some chopped mushrooms and parsley.

APPLE CHARLOTTE.—Line a buttered loaf tin with thin slices of home-made bread, dip the edges of the bread in white of egg, and fill the space with a smooth apple sauce seasoned with lemon rind and nutmeg or cinnamon; cover the top with strips of bread, put a small quantity of butter on top and bake one hour.

YELLOW JELLY.—Put an ounce of gelatine to soak in half a pint of water for an hour. Heat two cupfuls milk, add the gelatine, the beaten yolks of three eggs, a cupful of sugar and flavoring of vanilla. Boil it well, take from fire, whip up very stiff the whites of the the eggs, beat them into the jelly and pour into moulds to stiffen. Serve with thin boiled custard or sweet cream.

SPANISH FRUIT PUDDING.—Line a baking dish with a light puff paste, add a layer of shredded pineapple and cover it with powdered sugar, add a layer of sweet oranges sliced, strew over them a thin layer of sugar, next add a layer of sliced bananas with sugar strewn over them. Repeat the process until the dish is full. Cover the dish with a light puff paste, and bake to a delicate brown.

SPANISH ONIONS WITH EGGS.—Fry a Spanish onion cut into slices until it is done, in either oil or butter, then add a little flour and cook for a moment, add a little cream or milk sufficient to make a thick sauce, put in pepper, salt, a little grated nutmeg, and four hard boiled eggs cut into slices. Simmer until hot, then serve.

HAZELNUT CAKES.—Chop finely one pound hazelnuts, add one pound powdered sugar and two ounce flour, mix well and bake on buttered white paper, like macaroons, in a slow oven.

OPEN JOINTS IN DRAINS.—A suspected joint in a sewer or drain pipe may be tested by wrapping it with a single layer of white muslin moistened with a solution of acetate of lead. As the gas escapes through the meshes of the cloth it will be blackened by the sulphur compound.

SMELL OF PAINT.—On closing the premises at night, place on a stone in the centre of the floor a pan of lighted charcoal, on which a handful of juniper berries have been thrown. Leave this until the following morning, and when the doors are opened all the disagreeable vapors will disappear. Another method is to use a pail of water in which a bunch of hay is soaking, but this takes a longer time to effect the same result.

NEW MARKINGS.—Mr. A. Stanley Williams, of Burgess Hill, Sussex, has discovered three delicate but distinct markings in the equatorial region of Saturn. The first and third of these are round bright spots, somewhat brighter than the white equatorial zone in which they occur. The second is a smaller dark marking on the equatorial edge of the shaded belt which forms the southern boundary of the white zone. Mr. Williams has obtained abundant proofs of the reality of these markings but points out that it requires patience and practice to see them readily.

ALUMINUM MOTOR.—J. W. Hanson, a jeweler in St. Paul, Minn., and formerly a resident of Cincinnati, is having an electric motor made out of aluminum by a Sixth Street model making firm. It will be the first motor ever made of this new metal. It is gotten out on an entirely new design, occupies a small space, and is very light, yet accomplishes as much as an ordinary motor. Thus an ordinary motor may weigh 100 pounds or more, yet this weighing 20 or 30, being a quarter less than the ordinary, possesses great advantage in lightness. A boy can walk off with it.

WOODS THAT SINK.—There are 413 species of trees found within the limits of the United States and territories, sixteen of which, when perfectly seasoned, will sink in water. The heaviest of these is the black ironwood (*Condalia ferrea*), found only in Southern Florida, which is more than 30 per cent. heavier than water. Of the other fifteen, the best known are the lignum vitæ (*Guaiacum sanctum*) and the mangrove (*Rhizophora mangle*). Texas and New Mexico lands, full of queer, creeping, crawling, walking, and inanimate things, are the homes of a species of oak (*Quercus grisea*), which is about one and one-fourth times heavier than water, and which, when green, will sink almost as quickly as a bar of iron. It grows only in mountain regions, and has been found westward as far as the Colorado desert, where it grows at an elevation of 10,000 feet.

BOYS AND BONES.

A SCHOOL-BOY'S CONCEPTION OF HIS SKELETON.

The following composition, says Harlan H. Ballard, in the *Popular Science News*, was actually written for a school exercise, and is so amusing and bright that it was handed me by the teacher. The writer is not a member of the Agassiz Association, but he ought to be!

BONES.

Bones are the framework of the body. If I had no bones in me I would not have as much shape as I have now. If I had no bones in me I should not have so much motion, and grandmother would be glad, but I like to have motion. Bones give me motion because they are something hard for motion to cling to. If I had no bones, my brains, lungs, heart, and large blood-vessels would be lying around in me and might get hurted, but now the bones get hurted, but not much unless it is a hard hit. If my bones were burned I should be brittle, because it would take the animal out of me. If I was soaked in acid I should be limber. Teacher showed us a bone that had been soaked. I could bend it easily. I would rather be soaked than burned. Some of my bones don't grow close to my body, snug, like the branches of a tree, and I am glad they don't, for if they did I could not play leap-frog and other nice games I know. The reason why they don't grow that way is because they have joints. Joints is good things to have in bones. There are two kinds. The ball and socket, like my shoulder, is the best. Teacher showed it to me, only it was the thigh bone of an ox. One end was round, smooth, and whitish. That is the ball end. The other end was hollowed in deep. That is the socket, and it oils itself. It is the only machine that oils itself. Another joint is the hinge joint, like my elbow. It swings back and forth, and it oils itself. It never creaks like the school room door. There is another joint that don't seem like a joint. That is in the skull. It don't have no motion. All my bones put together in their right places make a skeleton. If I leave any out, or put any in their wrong places, it ain't no skeleton. Cripples and deformed people don't have no skeletons. Some animals have their skeletons on their outside. I am glad I ain't them animals; for my skeleton, like it is on the chart, would not look well on my outside.

FALLING STARS.

THE PRESENT STAGE OF OUR KNOWLEDGE OF METEORS.

Meteors, by which we mean especially the shooting and falling stars and fireballs, and the aerolites that sometimes fall to earth from interplanetary space, belong in many respects to the problematical phenomena of the heavens. Shooting stars are luminous objects that can be seen on any clear night darting through the sky, leaving a trail of light that lasts some seconds when the meteor is particularly bright. The record of observations made by J. Schmidt shows that the average number visible to a single person in the space of one hour is ten; that the average number can be seen between eleven o'clock and midnight, while the mean maximum frequency occurs at three o'clock in the morning; and that the frequency varies in different months of the year, being greatest in August and least in February. The number visible to the naked eye from all points of the earth's surface would on this basis average 450,000 per hour. The highest number that a single person has counted in an hour is 2,000. There are nights when these meteorites appear in swarms. Star showers occurring at irregular intervals are to be distinguished from the periodical phenomenon of the Leonids, or November meteors, which have been observed on different years at the same date—between the 12th and 15th of November. Periodicity has been noted in other showers; particularly those that occur between the 9th and 14th of August, which have been called, from the part of the heavens whence they appear to radiate, the August Perseids. Denning has established beyond doubt the existence of another periodical shower, the July Perseids, observable on the nights between the 26th and 30th of July, and likewise appearing to issue from the constellation of Perseus. At the same period of the year occurs the more brilliant shower of the Aquariads, which apparently emerge from Aquarius. Between the 20th and 25th of April occur the Lyraids, and a number of other similar periodic showers have been noted. The phenomena do not show the same striking beauty every year. For the Leonids a period of 33.28 years has been determined; for the August Perseids a main period of 104.06 years, and a minor period of 8.05 years; for the Lyriads a main period of 42.07 years, and a minor period of 7.01 years. It is doubtful whether the epoch of their return varies in the course of time, and it is certain that the conclusion of Coulvier-Gravier that the November and August showers are in the process of extinction is without foundation. Sporadic falling stars, as Julius Schmidt's observations at Athens have proved, are more numerous in the latter half of the year than in the earlier half. The Milan astronomer, Schiaparelli, explains this, and the fact that their frequency depends on the hour of the night, but not at all on the longitude of the point of observation. Supposing the meteorites to be minute bodies suspended in interstellar space, the question arises, What action would the earth have upon those that it strikes in its path around the sun? Encountering the face of the globe that is at any instant the forward one in the orbit, they are most commonly seen in the hours just preceding the dawn. The ecliptic, the eccentricity of the orbit, the variations of the seasons, and the geographical latitude must also be taken into account, and this explains the exceptions to the rule. In these latitudes the point toward which the earth is moving is much higher above the horizon in the second half of the year, and hence at that time more meteors are visible because they are not obscured by the vapor

Buffalo Lithia Water, Spring No. 2, in Bright's Disease, Gout, Stone in the Bladder, and Diseases Generally of Uric Acid Diathesis, Etc., Etc.

DR. WM. A. HAMMOND, of Washington, D. C., Surgeon General U. S. Army (retired), Professor of Diseases of the Mind and Nervous System in the University of New York, etc.

"I have for some time made use of the BUFFALO LITHIA WATER in cases of AFFECTIONS of the NERVOUS SYSTEM, complicated with BRIGHT'S DISEASE OF THE KIDNEYS or with a GOUTY DIATHESIS. *The results have been eminently satisfactory.* Lithia has for many years *been a favorite with me in like cases, but the* BUFFALO WATER CERTAINLY ACTS BETTER THAN ANY EXTEMPORANEOUS SOLUTION of THE LITHIA SALTS, and is, moreover, better borne by the stomach. I also often prescribe it in those cases of CEREBRAL HYPERÆMIA resulting from OVER MENTAL WORK—in which the condition called NERVOUS DYSPEPSIA exists—*and generally with* MARKED BENEFIT."

DR. WM. B. TOWLES, Professor of Anatomy and Materia Medica, in the Medical Department of the University of Virginia.

"BUFFALO LITHIA SPRINGS, No. 2, belongs to the ALKALINE OT, *perhaps, to the* ALKALINE SALINE Class, *for it has proved far more efficacious in many diseased conditions than any of the simple* ALKALINE waters.

"*I feel no hesitancy whatever in saying that in* GOUT, RHEUMATIC GOUT, RHEUMATISM, STONE *in the* BLADDER, and in all diseases of URIC ACID DIATHESIS, *I know of no remedy at all comparable to it.*

"*Its effects are marked in causing a disappearance of* ALBUMEN *from the urine. In a* single case of BRIGHT'S DISEASE *of the* KIDNEYS, I witnessed *decided beneficial results from its use, and from its action in this case I should have great confidence in it as a remedy in certain stages of this disease.* In DYSPEPSIA, especially that form of it in which there *is an excessive production of* ACID *during the process of nutrition*, in some of the PECULIAR AFFECTIONS *of* WOMEN, notably in SUPPRESSION of the MENSES, and in CHRONIC MALARIAL POISONING, etc., I have found it highly efficacious."

DR. G. HALSTEAD BOYLAND, late Professor of Surgery, Baltimore Medical College, late Surgeon French Army (Decorated), Member Baltimore Academy of Medicine, Member of American Medical Association.

"In BRIGHT'S DISEASE of the KIDNEYS, ACUTE or CHRONIC, BUFFALO LITHIA WATER, Spring No. 2, is, in my experience, *without a rival*, whether in the PARENCHYMATOUS form or INTERSTITIAL NEPHRITIS. In cases in which the ALBUMEN in the URINE reached as high as 50 per cent., I have known it under a course of this water gradually diminish and finally disappear, at the same time other alarming symptoms were relieved and the sufferers restored to health.

"In STONE in the BLADDER of the RED LITHIC ACID and the WHITE PHOSPHATIC DEPOSIT, the SOLVENT power of this water is *unmistakable.*"

Water in cases of one dozen half gallon bottles, $5.00 f. o. b. here.

THOS. F. COODE, Proprietor, BUFFALO LITHIA SPRINGS, VA.

contained in the lower atmosphere. The average brightness of meteors is about the same at all the hours of the night, and is somewhat less in February than in August and November. The apparent path of a meteor is usually a straight line, although Heir has observed wavy, sinuous and crooked paths. They appear to be moving downward as a rule, more seldom upward, and very rarely they take a horseshoe curve, first rising and then falling. Their occasional irregularity of motion is accounted for by unsymmetrical forms, causing them to act like boomerangs or other irregular projectiles. The apparent course gives no indication of the actual path. For the northern hemisphere Heir has located 84 radiating points for sporadic shooting stars, while Greg distinguishes 77 such regions in the heavens; Schmidt, 150; Schiaparelli, 189; and Denning 37 particular points. Careful studies of J. Schmidt show that the active radiants exhibit an increase in the frequency of meteors up to two o'clock every night, and that they remain constant from January till July, and then rapidly increase. Of their orbits and the relations of their planes to that of the earth's orbit, and of their periods of revolution, no calculations are possible, except in the cases of remarkably bright meteors that are obscured in many different places. The November and August star showers, by reason of their periodicity, admit of closer calculations. It may be assumed that these streams of meteorites move in an elliptical orbit, having the sun for one of its foci. The August stream is supposed to be a complete elliptical ring, into which the earth plunges every year on the 10th of August. It is continuous, for the phenomenon recurs annually, but not equal throughout its length, for in some years many more meteors are seen than in others. The perihelion is about equidistant with the earth from the sun and the aphelion is a third farther away than Neptune. The ring revolves in a direction opposite to the earth's orbit, which it crosses near the perihelion. A complete revolution is made in from 113 to 123 years. The November stream is not a ring, but a long swarm, which also moves in a direction contrary to the earth's motion, and completes its elliptical course in 33¼ years, reaching in aphelion the orbit of Uranus. Sporadic meteors can follow no regular path, owing to the disturbing influence of the planets. They may be taken to be members of the streams that have been deflected from the regular course by planetary attraction. The velocity of shooting stars is reckoned by Heir at five or six miles a second, and by others at nine miles. This high velocity is a strong proof of their cosmic origin. Meteors are first visible when fourteen or fifteen miles, and sometimes even thirty-five miles, above the earth's surface, and reach in their flight to within nine or ten miles of the surface, some even as close as three miles; but it is not always the brightest that come nearest. It follows that the earth's atmosphere, the friction of which makes them luminous, must extend much higher than can be reckoned from the phenomena of twilight, but is rarefied beyond any conception at the higher altitudes. Meteorites have been calculated by the uncertain methods pursued by H. Herschel to range in weight from six grammes to two or three kilogrammes. In color 76 per cent. are white, 16 per cent. yellow, 6 per cent. red, and 2 per cent. green.—*Die Natur, June*, 1891.

Exhaustion

Horsford's Acid Phosphate.

The phosphates of the system are consumed with every effort, and exhaustion usually indicates a lack of supply. The Acid Phosphate supplies the phosphates, thereby relieving exhaustion, and increasing the capacity for labor. Pleasant to the taste.

Dr. A. N. KROUT, Van Wert, O., says:
"Decidedly beneficial in nervous exhaustion."

Dr. S. T. NEWMAN, St. Louis, Mo., says:
"A remedy of great service in many forms of exhaustion."

DESCRIPTIVE PAMPHLET FREE.

RUMFORD CHEMICAL WORKS,
PROVIDENCE, R. I.

BEWARE OF SUBSTITUTES AND IMITATIONS.

CAUTION:—Be sure the word "Horsford's" is *printed* on the label. All others are spurious. Never sold in bulk.

BUSINESS NOTES.

HORSFORD'S ACID PHOSPHATE

Makes delicious lemonade. A teaspoonful added to a glass of hot or cold water, and sweetened to the taste, will be found refreshing and invigorating.

NEW SCHOOL.—The American Electro-Therapeutic Association will hold its first annual meeting at the hall of the College of Physicians, corner Locust and Thirteenth streets, Philadelphia, Pa., Thursday, Friday and Saturday, September 24th, 25th and 26th, 1891, under the presidency of Dr. G. Betton Massey.

LARGE RUBIES.—Three rubies of unusual size were sold at auction in London recently. They were the property of the Burmah Ruby Mine Company, Limited. The first, weighing 1,185 carats, irregular in form and deep red in color, sold for £400. The second, yellowish red in color, weighed 302 carats, and sold for £65. The third weighed 281 carats, was dull red in color, and brought £33 12s.

HOW IT ACTS.—Water extinguishes fire, not, as the common talk is, by virtue of any incompatibility between the two elements, but partly by the effect of the lowering of the temperature caused by its evaporation, and partly by acting as a mechanical extinguisher. Enveloping the parts of the body upon which it is thrown, it separates the combustible matter from the atmosphere, and cuts off the supply of oxygen, the life of the fire.

DEPTH OF THE INDIAN OCEAN.—An area having depths of 3,000 fathoms and more exists off the northwest coast of Australia. In addition to earlier observations between meridians of 100 and 106 degrees E. and parallels of 18 and 25 degrees S., new results were obtained in 1888 by the Eastern Telegraph Co.'s steamship Recorder, under Captain C. O. Madge. The depths found were from 3,015 to 3,393 fathoms, between the latitudes 13 degrees 40 minutes and 11 degrees 22 minutes, and the meridians 118 degrees 42 minutes and 116 degrees.

EARTH ODOR.—M. Berthelot has been investigating the cause of that peculiar and far from unpleasant odor which arises when vegetable soil is moistened. It proves to be produced by a camphor-like substance existing in extremely minute proportions—only a few millionths—exact analysis of which has not been practicable, on account of the small quantity obtainable. The author did not find the alcohol in the soil that M. Muntz claims to have detected there, and regards that found by M. Munts as only an exceptional product of the spontaneous fermentation of vegetable *debris*. The new odoriferous body has a similar action with alcocol in producing iodoform.

ORIGINAL. No. 53.

Luncheon Muffins.

BY MARIA PARLOA.

For one dozen muffins use one pint of flour, a generous half pint of milk, two teaspoonfuls of Cleveland's Baking Powder, half a teaspoonful of salt, two tablespoonfuls of sugar, three tablespoonfuls of butter and two eggs. Mix the dry ingredients together and rub through a sieve. Melt the butter. Beat the eggs till light and add the milk to them. Add this mixture to the dry ingredients; then stir in the melted butter. Beat the batter vigorously for a few seconds and then put in buttered muffin pans and bake for about twenty minutes in a quick oven.—(Copyright, 1891, by Cleveland Baking Powder Co.)

Use only Cleveland's baking powder, the proportions are made for that.

Cleveland's Superior Baking Powder is perfectly wholesome. It leavens most and leavens best.
Try a can.

25 CTS. PISO'S CURE FOR CURES WHERE ALL ELSE FAILS. Best Cough Syrup. Tastes good. Use in time. Sold by druggists. CONSUMPTION 25 CTS.

PURE PEPSIN

In Powder and Scale.

MANUFACTURED BY

ARMOUR & COMPANY, Chicago.

Guaranteed free from adulteration or make-weights; of excellent physical properties and high digestive power.

Under similar conditions, **ARMOUR'S PEPSIN** will exhibit greater activity than any other pepsin now before the profession.

The Manufacturers will be pleased to supply members of the Medical Profession with samples of their pepsin, and with full details regarding digestive strength, if desired.

SEE PAGE 404 FOR VALUABLE OFFER.

THESE OFFERS WILL BE WITHDRAWN SEPTEMBER 1, 1891.

WATCHES.

EVERY one wants a watch, and naturally a good watch that keeps accurate time, presents a handsome appearance, and is inexpensive. If such a watch can be found of American manufacture, it is an additional appeal to our patriotism. Just such a watch as this ideal THE ANALYST PUBLISHING COMPANY is enabled to offer as a Premium to its readers. Having some large advertising contracts we have been enabled to procure the movements of the manufacture of the best known American watch factories, namely, the Waltham, Elgin, Hampden and Illinois Watch Companies. These movements are adapted for both ladies' and gentlemen's watches, and are warranted by the makers. These movements have seven jewels, patent lever movement, chronometer balance, patent safety pinion, sunk hard-enameled dial, straight line visible palette, stem winders, hand set; in fact, contain all the latest improvements and can be readily cleaned or repaired by any ordinary good watchmaker. They can be regulated to run as close as any movement.

It is needless to say that to case these movements in solid gold cases would make them too expensive, yet they are cased in what are known as gold filled or stiffened "Ladd" cases, and are warranted to be 14 karat gold, made from two sheets of 14 karat gold overlaying fine composition metal, with regular jointed caps, covers and bezels, and to wear at least five years. They are not plated, nor rolled gold, but actual 14 karat gold cases, thin of course, but stiffened and strengthened by being filled with this fine composition metal. They are finished in the same manner, engine turned and engraved as solid gold watches, and wear and look just the same. No one but an expert can tell them from a solid gold watch. These watches are made both open face and hunting case style, in gentlemen's or ladies' sizes. For gentlemen we recommend plain engine-turned cases; for ladies, a handsomely engraved case.

How to Obtain One of these Watches.

These watches are not to be purchased from us at any price. Send us a club of 25 subscribers to the AMERICAN ANALYST, and $25, the regular subscription price, and one of these watches (your choice of style and size) will be immediately forwarded, post-paid and registered, to your address. You need not wait until you have your 25 subscribers all together, but forward them as you get them and they will be credited to you, and when the number is complete the watch will be sent. A subscription for two or three years will be counted as two or three subscribers.

As these watches are retailed by jewelers at not less than $25, it will be seen that we are offering a real premium with the sole object of increasing our circulation, and that by taking advantage of our offer any one can obtain a good, reliable and handsome watch without cost. As the number of these watches at this price is limited, it is advisable to take steps at once to procure a bargain.

THE ANALYST PUBLISHING CO., 19 PARK PLACE, NEW YORK.

BICYCLES

GIVEN AWAY TO BOYS AND GIRLS!

AN OPPORTUNITY OPEN TO ALL.

The Analyst Publishing Company being desirous of largely increasing their subscription list, will furnish every one with a beautiful Safety Bicycle, ABSOLUTELY FREE, in return for a few hours' canvassing.

To every boy and girl who secures 75 subscribers for the American Analyst at $75, we will give a splendid

$40.00

NONPAREIL

SAFETY BICYCLE.

These bicycles are adapted in size to boys, but are strong enough to carry a man. A boy's bicycle should be a strong one. They are manufactured by the OVERMAN WHEEL CO., the makers of the celebrated VICTOR Bicycle, and have the full guarantee of the makers.

The following is a brief description of the NONPAREIL SAFETY; 26-inch wheels; ball bearing all around, including pedals; solid crescent rims; double tangent spokes; three-fourths inch tires; cranks, three throw, $4\frac{1}{4}$ to $5\frac{3}{8}$ inches; guards to both wheels; tool-bag, oiler and wrench. Finished in bright enamel, all exposed metal heavy nickel-plate on copper.

In selecting these machines as a premium, we have disregarded cheapness and selected a Bicycle which is serviceable, and the makers of which have an established reputation for building the best Bicycle that money, machinery and brains can produce. We are actually furnishing the Bicycles and Papers at less than cost, but hope by stimulating active and successful canvassing, and thus enlarging our subscription lists, to make an eventual profit. We positively guarantee these bicycles to be just as here represented. They will be shipped by express f. o. b. in New York.

Subscription orders must be made out plainly and legibly, and sent as fast as secured, addressed to

THE ANALYST PUBLISHING CO., 19 Park Place, New York.

TO ADVERTISERS.

It is now nearly seven years since the AMERICAN ANALYST began its mission as an advocate of pure food and an opponent of sham products. The history of its labors in that field, even if confined to a reviewal of the success it has achieved in exposing and defeating unscrupulous schemes involving risk to the health and depletion to the purse of the public, would require greater space to rehearse than is available within the limits of this page. As we have heretofore had occasion to explain, in relation to the purposes of this journal, humbugs seeking to enrich themselves through the sale of high-sounding specifics for various human ailments, are subjected to the crucial test of thorough chemical analysis of their goods; and where the latter, as too frequently occurs, prove to be frauds, the facts are placed before our readers in order to save the public from further unconscious imposition. The AMERICAN ANALYST, in addition to the warfare it wages against that species of malefactor, co-operates regularly with the Boards of Health of this and other cities in efforts to secure sanitary and food reforms through organized efforts, and it is conceded to be the only popular medium through which those bodies can bring their purposes and action intelligently before the general public. Reaching as it does all classes—manufacturers, merchants, physicians, chemists, and private families—all over the land, its influence is exerted over a vast radius, producing results as visibly marked as they are wide-spreading. The scope of this journal, however, is not limired to the missionary work above described. Its varied contents cover almost the entire field of scientific as well as social progress, and each yearly volume constitutes a compendium of current facts in nearly every department of knowledge such as can nowhere else be obtained in such comprehensive shape and so cheaply. In this relation we take occasion to publish here a few extracts from a large number of similar compliments that we have received from strangers as well as from our regular patrons. A New Haven editor writes: 'As a newspaper man, and one with a strong, active instinct for good miscellany matter, I want to congratulate you on your publication. The ANALYST is certainly a unique and valuable periodical, and I feel sure that if you press its sale you will gather in thousands who are waiting only to see it before subscribing." A London editor writes us: "I have just seen your excellent paper for the first time, and I am quite delighted with it. I wish you would exchange it for my magazine." A New York journalist, one of the most famous in the profession in America, bore down upon us with the following unexpected praise: "I cannot refrain from congratulating you on the ANALYST. Its brainy suggestions make it one of the most welcome of my exchanges." A well-known scientist says, in the course of a letter on other subjects: "Part of my leisure this summer has been devoted to cutting up my files of scientific papers. It may please you to know that I was astonished to find how perfectly you have kept the ANALYST abreast of scientific thought. It is indeed a valuable paper, and I congratulate you on your success in making it so worthy an addition to technical literature." These extracts will suffice to show the estimation in which the AMERICAN ANALYST is held by experts familiar with its purposes and methods. It is essentially a paper for the family, and with the low subscription price of only one dollar, it ought to find regular and welcome lodgment in every household in the United States.

HAMMOND'S
CELEBRATED

TABASCO PEPPER SAUCE,

OR LIQUID PEPPER.

Is simply the Pulp of the Ripe Pepper Extracted by Pressure.

The seed of this Pepper was obtained from Central America, and by careful cultivation in Louisiana for many years has been so improved in strength, flavor and aroma, as to have become a new variety of Red Pepper, superior to all others. The pulp is so handled as to retain all the flavor, strength, aroma and color of the ripe fruit, and to keep unimpaired in any climate. It excites the appetite, promotes digestion, and is pronounced by connoisseurs to be the finest condiment in the world. For medicinal purposes it recommends itself by its purity, strength and diffusible form.

Manufactured by E. McILHENNY'S SON,

NEW IBERIA, LA.

For Sale by all Wholesale Grocers.

To Subscribers, Readers and Advertisers.

SUBSCRIBERS' attention is called to the great variety of interesting and instructive subjects treated in this number. We respectfully ask the co-operation of our subscribers in extending our Subscription list, which will enable us still further to increase the value of the AMERICAN ANALYST to them.

The CASUAL READER is specially requested to examine our liberal premium offer.

ADVERTISERS who do not know of this Journal already, are respectfully referred to article headed "A Business Benefit."

ALL are kindly requested to peruse this number thoroughly.

The AMERICAN ANALYST can be had at any news stand in the United States. Any newsdealer will take orders for it, the American News Company being our wholesale agents. All postmasters will receive subscriptions.

NATRONA BI-CARBONATE OF SODA.

(ABSOLUTELY PURE.)

The nature of the raw material from which NATRONA BI-CARBONATE OF SODA is made—viz., kryolith, a mineral containing *pure sodium*—insures a purity and uniformity of product which cannot be obtained from any other known material. In making BI-CARB. SODA from any other raw material, the use of sulphuric acid is a necessity, but none is used in any part of the process of making NATRONA BI-CARB.; hence its entire freedom from the slightest trace of arsenic, which is always present in ordinary soda. Its absolute purity and entire freedom from all traces of *sulphate of soda*, common salt and other impurities, render NATRONA BI-CARB. NEARLY TASTELESS, and being bolted through the finest bolting-cloth, insures the finest stage of division.

To these indisputable facts the attention of CONSUMERS of soda is specially called. They are IMPORTANT, and should influence both those who use and those who sell soda, to buy and sell NONE BUT THE BEST.

The NATRONA BI-CARB. Soda is kept in stock by almost every wholesale druggist and grocer throughout the United States, of whom it may be ordered.

Natrona Bi-Carb. Soda is unequaled by any other brand of English or American Manufacture.

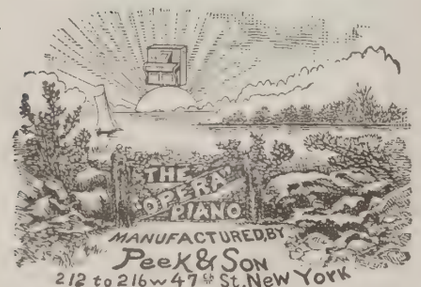
DO YOU KNOW THE **DANGER** OF USING SOAP?

IF YOU ARE GOING TO THE COUNTRY, DO NOT FAIL TO READ THE FOLLOWING.

WE do not mean soap made from proper material; and when we tell you that about ninety-nine per cent. of Toilet Soap is made from refuse fats gathered from tenement houses, hospitals, butcher shops, and from cattle dying of disease or during transportation, you will, we believe stop and think. Putrefactive changes have taken place in most of this material, as it is mixed with lean meat, blood, bones, sinews, etc. There is at least *one* soap that is made wholly from vegetable material—OLIVE and PALM OILS—and that is



VELVET SKIN SOAP.

It will keep the skin soft and in a healthy condition, as no animal fats are used in its manufacture. Nothing in one's personal outfit is quite so satisfactory as a thoroughly reliable Toilet Soap. We are confident that a trial of this article will insure its continued use. If the dealer does not keep it, do not take any other, but require him to order it for you, which he can do readily. **Otherwise, send to us direct.**

THE MICROSCOPE IN COURT.

The superiority in producing romantic incident of truth over fiction has been too long established to justify its mention otherwise than in casual reference to it as a universally conceded fact. It is this concomitant of human every-day experience that furnishes most of the material, popularly styled "sensational," of which so much is made by the enterprising newspapers of the present period. The records of our law tribunals, the criminal courts especially, are replete with incident of the exciting character referred to, and the jaded novelist, weary of racking his brain for new suggestions for his plots, might there find an inexhaustible fund of material covering every possible phase of passion and sentiment, and of variety as infinite and complex as the ineffable operations of the heart and mind of humanity. For some reason, however, which it would be out of place to investigate here, the domain to which we refer does not seem to attract the attention of novel writers to the extent that might be expected of a field so fertile, except when some intellect like that of Wilkie Collins or of Charles Reade displays its masterly power by weaving into a semblance of fiction the threads of romance that surround us constantly in real life, but whose capacity to thrill the heart and excite the imagination is revealed to only genius of that high and exceptional order. Our attention has been attracted to the subject by a paper read, on August 11th, at the annual meeting at Washington, D. C., of the American Society of Microscopists. A gathering of that prosaic kind would hardly be looked to as a fountain-head of romantic suggestion, and yet, incongruous as it may appear, the essay in question, treating of the most serious facts, embodies every quality essential for the construction of the most sensational story imaginable. In the narrative it unfolds we perceive the technical skill and constructive aptitude of the trained scientist operating in conjunction with the ratiocinative logic of a Poe and the ferret-like instinct of a Gaboriau in tracing to their starting point, through an apparently impenetrable labyrinth, the threads of a terrible tragedy, with the happy and unanticipated result of establishing the innocence of a man nearly convicted of murder, and of throwing open the prison gates from which it had appeared, after a year of unjust incarceration, there was to be no outlet except to the gallows. In the accomplishment of this brilliant outcome the microscope was the chief instrument used, its skilful manipulator being Dr. Frank L. James, the distinguished president of the National Association above mentioned. The use of the microscope for facilitating the ends of justice is growing with the gradual perfection of the instrument, and with the advanced knowledge of its value and capability for working it which the Microscopists' society is effectively cultivating. A generation ago it was popularly esteemed a toy, its serious import being appreciated by only a few enthusiasts. To-day it stands high as an instrument of accuracy, as it places before our senses its wondrous revelations of a hitherto invisible world. In a recent famous criminal trial in this city it alone furnished what was accepted as the convicting link between a murdered woman and the instrument of her assassination. In the other case referred to it produced the only testimony that saved an innocent man from the gallows. "*Tantum series juncturaque pollet*," said Horace, of old, which we may interpret to mean, "Such power is there in the proper arrangement and skilful combination of reason and science." We regret that we are unable to give here the details of the trial for murder of Charles F. Vail, in St. Louis, but the interest of the narrative rests wholly upon the really wonderful manner in which inductive reasoning, fortified at each step by the results of a series of ingenious experiments, was competent to extort from mute matter a chain of incontrovertible facts that upset the whole fabric which the prosecution had laboriously contrived. The mere recapitulation of these would fill upwards of three pages of this journal, that being the space accorded to them in the *National Druggist*, from which we derive our acquaintance with the case. We understand that the entire paper will be published in the forthcoming volume of proceedings of the American Society of Microscopists, fully illustrated with photographs and drawings. The case will unquestionably take high rank among the *causes celebres* in which the microscope has been conspicuously employed, and some of its features at least will be utilized by our fiction mongers.

ELECTRIC LIGHT PROSPECTS.

Experiments recently conducted by Mr. Nikola Tesla for the purpose of showing how houses can be electrically lighted by lamps with one wire, or even with no wire at all, have produced a great sensation in Europe. Mr. Tesla showed that Geissler tubes three feet long were converted into brilliant beams of light by being held near a coil or a large sheet of tin plate connected with a pole of an alternating machine, and he remarked that if he had time at his command to make the necessary preparations he could have produced an electrical field capable of lighting up the whole of the lecture hall by means of similar tubes suspended at intervals from the ceiling. It is generally believed that the results obtained by Mr. Tesla will within a very short time lead to a complete revolution in the artificial production of light, and that we stand on the threshold of discoveries even more startling and possibly more momentous than the invention of the dynamo or the telephone.

IMPORTANT DISCOVERY.

We learn by our English exchanges that it has just been discovered that the standard yard, and certain other measures and weights supposed to have been lost when the houses of Parliament were destroyed by fire in 1834, are still in existence. For over half a century they have lain in the Journal office, almost unnoticed, and but for some inquiries recently set on foot by Mr. Bull, the chief clerk, respecting the present standards, they might have remained unnoticed for a much longer period. A reference to the contemporary records shows that after the fire the standard bars of 1758 and 1760 were both found among the ruins, "but they were too much injured to indicate the measure of a yard which had been marked upon them." The principal injury to both of the standards was the loss of the left-hand gold stud, but whether this was caused by the action of the flames or otherwise is not known. The most important standards thus rescued from oblivion are the yard measures constructed by Bird in 1758 and 1760. The former was copied from a bar in the possession of the Royal Society, which was itself a copy of a standard preserved in the Tower; and the second was constructed under the directions of a committee of the House of Commons from the 1758 standard. "Each of these

two standard yards consisted of a solid brass bar 1.05 in. square in section and 39.73 in. long. Near each end of the upper surface gold pins or studs 0.1 in. in diameter were inserted and points or dots were marked upon the gold to determine the length of the yard." The other standards in the custody of the Journal office are two brass rods answering the description of the old exchequer yard, and four weights supposed to be certain of the "copies, models, patterns, and multiples" ordered by the House on May 21, 1760, "to be locked up by the clerk and kept by him." The most important weight—the standard troy pound—is not amongst those now brought to light.

CONTEMPORANEOUS COURTESIES.

In our issue of July 2 (page 317), we reprinted from the *Journal of Commerce* of this city a very interesting article on the subject of "Superstition." By some inadvertence, or oversight in the correction of the proof sheets of the issue in question, the credit to that paper was omitted. No complaint has been made of our thus unintentionally appropriating our contemporary's wisdom, nor do we suppose the fact has been noticed, but we take this opportunity of expressing regret for the circumstance, as it is our invariable custom, or purpose, at least, to give honest credit for all borrowed material. We should be gratified if we could elicit similar courtesy towards ourselves from some of our esteemed contemporaries.

BOTANIC FREAKS.

SOME OF THE WONDERS OF THE NATIONAL GARDEN.

A new species of vegetable whiskey-shop has been added to the collection of plant curiosities in the National Botanic Garden in Washington, writes Rene Bache. The liquor it distils in the pitcher-shaped receptacles that hang from its stems is especially liked by frogs, which hop into these traps for the purpose of drinking it. Although the sweetish fluid is a powerful intoxicant, the batrachian customer, however wildly over-stimulated, would certainly jump out again were it not that two very sharp, dagger-like thorns project downward from the lip of the vessel in such a manner that Mr. Frog, in trying to escape, is thrust through the body by them at every leap, until presently he falls dead in the "liquid refreshment"—an appropriate object lesson to all intemperate persons—whereupon the plant absorbs his substance, as the ordinary whiskey-shop consumes that of its frequenter, and is thus supported. This species is tropical, and has to be kept in the greenhouse devoted to plants of the equatorial belt. Naturally, there are no frogs in the conservatory, and so Superintendent Smith is obliged to feed this eccentric vegetable with raw meat chopped fine, on which it thrives excellently. For lack of insects, likewise, he supplies with the same artificial sustenance the other sorts of whiskey-shops that find in bugs of various descriptions their chosen prey. They will all eat beef, although each variety seems to have in nature its particular line of customers, one capturing cockroaches, another ants, and so on. Doubtless they all could live on any animal food, but there seems to be a difference of taste among the insects as to the liquors. One species will only touch the drink served by a certain representative of this carnivorous plant family; another selects by preference a different brew, and so on. Thus but one sort of bug is ordinarily found in each set of pitchers, those designed for the accommodation of large beetles and cockroaches being as big as small shoes. It is very curious to cut open one of these vessels after it has become withered and dead, being merely formed at one end of the leaf, and to find what a wonderful collection of victims it has gathered in and not finally digested, often numbering many hundreds, if the prey is small. The whole structure of each trap is beyond measure curious, the inner surface of some coated with little bristles that project downward, and prevent the guests so hospitably received from walking out again. This is particularly a feature of what the superintendent calls the vegetable lager beer saloons, which prepare a liquor of much less intoxicating quality in tall chalice-shaped vessels instead of pitchers, depending upon drowning their customers rather than upon making them so drunk that they cannot get away. A deplorable thing it seems, by the way, to find such bad habits prevalent among bugs, the opinion having been always held that only man—the most noble of animals—had a right to indulge in vices, to the elaboration and invention of which he has given so much attention. A novelty at the Botanic Garden is a plant whose leaf bears a remarkably well executed caricature of the Duke of Wellington, all done in the veining; but in the interest of visitors it does not seriously rival either the "mother-in-law plant," a scrap of which swells up your tongue so that you cannot speak for days, or the famous "butcher plant" of Maryland, that has, instead of leaves, so many pairs of toothed jaws that close upon any insect venturing between to get at the sweetish bait within. This "butcher plant," which grows nowhere in the world save in the vicinity of Wilmington, Del., suffers from its carnivorous habits, being a chronic victim of indigestion. Each stomach trap, having used up most of the gastric juice which it secretes in digesting the first living prey caught, usually finds the second victim it captures disagree with it, and the third it is unable to assimilate satisfactorily. Then the trap turns from green to brown and dies, like any leaf, other fresh ones developing, meanwhile, to take up the work of gobbling. After all, this greedy vegetable is not nearly so bad as the "cruel plant," as it is called, whose flowers wantonly capture unsuspecting butterflies that alight to sip honey, and hold them until they are dead, when the grasp of the ruthless petals is relinquished and the luckless visitor is dropped on the ground. It is astonishing what intelligence many vegetables exhibit. Naturalists have come to be much inclined toward thinking that a plant really has thoughts. Its mind, as they conceive, is situated in the rootlet, which knows so well always what path to pursue through the soil in search of water. Plants even employ insects as their servants, in the work of reproducing their species, paying them wages in honey. Most vegetables combine the two sexes in one flower; but breeding "in and in" is no more healthy for them than it is for animals. One blossom must marry with another if the species is to be continued in a healthy way. So young Mr. Honeysuckle dresses himself in a spring suit of bright yellow, and perfumes himself deliciously for the purpose of attracting the gay butterflies that flutter around. He always provides a small store of nectar in a golden cup to offer any insect guest that may come his way. Presently a butterfly pauses to take a sip of the sweet liquor; but, in doing so, she cannot avoid getting some of the pollen on her head, and this she carries to another honeysuckle, where she stops for a second bit of refreshment, and incidentally rubs off some of the pollen upon its stigma. Thus is accomplished the marriage of the flowers. But the bee is the Cupid of the vegetable world, to whom is assigned most of this marrying and giving in marriage among the blossoms. There is one kind of orchid that depends altogether for the continuance of its species upon fights among bees. To a moral delinquency on their part it may be said to owe its survival entirely. The petals of each of its flowers are so bent as to form a sort of little tunnel, and to get at the honey a bee must go in at one end or the other. If nothing interferes, it will never come into contact with any of the pollen; but now and then it happens that it meets another bee, which has entered from the other side. Then there is a fight, and in the scrimmage the combatants get bounced around and are covered with the reproductive powder. However, in order to accomplish anything, one of these bees must go off and have the same sort of fight in another orchid blossom, so as to transfer a portion of the pollen to the stigma. Luckily this occurs often enough to perpetuate the plant. There is an extraordinary flower that grows in the hot and damp jungles of the Malay peninsula, where it is called by the natives the "wonder-wonder." It is a blossom, and nothing else, without leaves or stem, which grows out of the wood of decaying vines. This parasite is sometimes three feet across, its globular central cup having a capacity of six quarts. The strong odor it exhales resembles that of decaying meat so strongly that flies swarm upon it, and it secures fertilization through their means. A book might be made of the freak plants of the world. There is the vegetable boa constrictor of India, known as the "maloo climber," which twines about great trees and strangles them to death, so that they decay, fall, in and often leave the empty tower of climbers standing erect. An African nut called the "balanites" is used as a sort of natural bombshell; when filled with gunpowder and set off, it explodes with a loud report. The familiar Brazil nut grows in hard, spherical pods, each of which contains from eighteen to twenty-four of the triangular seeds that come to market. So beautifully are they packed by nature that no man has ever been able to put them back in their receptacle after once they have been taken out. In South America also there is a "cow-tree," which gives milk that is shown by chemical analysis to be of almost exactly the same composition as that of the cow, which it resembles to perfection in appearance and quality, tasting like sweet cream. Deep in the swamps and forests of the Island of Formosa grows a plant, the stems of which are filled with a fine white pith. This pith is cut by the Chinese into thin strips, and is called "rice paper." Bodies of the dead suspended within hollows of the "Baobab" tree that grows in Africa are transformed into mummies for all eternity without further process of embalmment. On the elevated barren plains west of the Volga grows a plant closely resembling a lamb, which was said by travellers of old to bend from the stalk, upon which it could turn, and feed upon the herbage about it, but when the grass died it perished from hunger. The likeness referred to is not to be denied, though its death when the grass dries up is due to the same cause that kills the other vegetation, namely, drought. Every one has heard of the famous "deadly upas tree" of Java, which was declared to grow in a desert all alone—no other plants around it, nor fish in the waters, nor animals of any sort, since even the birds flying over were killed by its effluvium. Criminals condemned to die, according to the story, were offered the chance to escape execution by going to the tree and collecting some of its poison. About two out of every score returned, and they reported having found the ground strewn with bones of their predecessors. Subsequent investigation has discovered a certain basis of truth in the tale, which lies in the fact that these upas trees grow in low volcanic valleys, rendered unwholesome by the sulphurous fumes escaping from crevices in the earth. Streams in such neighborhoods are so impregnated with sulphuric acid that no fishes can live in them. The tree's juice is very poisonous, but otherwise it is harmless. Most strange and grotesque of the plants at the Botanic Garden are the cacti. They would appear to to have been created by Nature in a freakish and irresponsible mood. One might imagine them to properly belong in some other world than this, only half alive as they seem, and assuming such extraordinary and even absurd forms. Certain naturalists have imagined that they must be relics of a vegetation belonging to a period long prior to the development of the plant-life familiar to the present generation. Their characteristic spines, entitling them to the name of vegetable hedgehogs, accentuate their impossibility as contemporary species. The larger forms, some towering to fifty feet in height, and other individuals weighing a

ton or more, plentifully adorn the Mexican landscape, which in many parts obtains an aspect extremely weird from these astonishing growths. That country, in fact, contains three-fourths of the entire number of varieties known. Nature provides the cacti with spines in order to save them from being eaten by animals. Horses are very fond of them, and will frequently devour them, after kicking off the prickly surface with their hoofs. It is from a species of cactus that cochineal is obtained, and for the purpose of gathering from it the insects so valuable in commerce, great estates are planted with it in the West Indies, Algeria, the Canary Islands and India. The plants are set out in rows, trimmed to the height of four or five feet. In August or September of each year is the season for what is called the "sowing," when the field hands attach to the cacti, by means of thorns, leaves covered with female bugs, which are thus left in order that they may produce their young. The latter quickly swarm over the plants, from which they are removed four months later with blunt knives. This process is a tedious one, seventy thousand being required to make a pound. Finally the insects are killed by immersion in boiling water, and dried in the sun, that being the condition in which they are exported. One of the most surprising curiosities in this branch of the vegetable kingdom is the "Old Man cactus," which derives its name from the silvery white hairs that cover the upper part of its stem, giving it a peculiar resemblance to the hoary head of an aged man. The hairs are, in reality, soft, weak spines. When the plant is grown in the house it is best accommodated in a glass case, inasmuch as dust will otherwise render the hairs dingy, and impart to the old gentleman a very disreputable appearance. RENE BACHE.

TEA, THEINE AND TANNIN.

A NEWSPAPER EXPERT'S VIEWS ON THE SUBJECT OF TEA DRINKING.

Our sometimes heavy but always profound contemporary, the *Journal of Commerce*, says: The discussions concerning the innocuous character of tea as a common beverage which filled the columns of newspapers some years ago, are once more revived in private circles, and we have received a number of communications asking an expression of our opinion on the subject. There is something to be said on both sides of the question. When properly made and served, the moderate use of tea is wholesome and to be commended. The average composition is carbo-hydrates (gum and sugar), 21 per cent.; fatty matters, 4; albumenoids, 15; tannin, 15 to 26; vegetable fibre, 20; mineral subtances, 5; water, 5; theïne, 2 to 3, and aromatic oil, 1 per cent. The last two are the features which give to the beverage its flavor and refreshing quality. The theïne of tea is so identical with the caffeïne of coffee that the most expert chemist cannot distinguish between them. The tannin gives to tea its astringency, and is the least desirable of its constituent elements. In Appleton's Encyclopædia there is a statement that "it is impossible to make really good tea with hard water." We think the writer never read in the history of New York the description of its earlier days, when the "tea wells" were the favorite resort of those who were longing for a delicious cup of that "which cheers and not inebriates." There was no fraud in the recommendation. The water from certain wells did produce a finer beverage than the contents of the ordinary bucket dipped in other localities. The secret was not far to seek, and the puzzle was solved when it was found that the water in question drew out all the theïne and oil, and much less of tannin than the fluid found elsewhere. It was hard and not soft water that made the tea so prized by the epicures of that olden time. When at its best the description of Lo Yu, given many centuries ago, does not exaggerate its excellent qualities: "It tempers the spirits and harmonizes the mind, dispels lassitude and relieves fatigue, awakens thought and dispels drowsiness, lightens or refreshes the body and clears the perceptive faculties." We may add that the gentle exhilaration which accompanies the moderate use of tea properly prepared is not followed by the depression or reaction which succeeds the use of alcoholic stimulants. On the other hand, as commonly made, boiling out the tannin to give it a high color and an astringent flavor, it produces cerebral excitement, promotes insomnia and nervous irritability, decreases the flow of saliva necessary to digestion, and thus brings on dyspepsia and constipation. The theïne of tea and the caffeïne of coffee are the alkaloid craved by almost every human system, and when unmixed with anything deleterious are always innocuous and universally refreshing. The aromatic oil does not add to the healthful quality, but does impart a more delicious flavor to the beverage. Tea should never be boiled under any circumstances whatever. As to the water to be used we have several remarks to make worthy of especial attention. Whether it is hard or soft is of less importance than how it is treated. Where houses are furnished with hot and cold water the average cook, if left to herself, will fill the tea kettle from the hot water faucet in the kitchen. We know that when questioned she will deny it, but she does it, notwithstanding the disclaimer, always when she is in a hurry, and nine times out of ten even when she has abundant leisure. When we state that fresh water boiled fifteen minutes and then left standing in the kettle half an hour will not by any possibility whatever produce a cup of tea fit to be drank, what may be said of tea made from water that has "sizzled" in a boiler for twenty-four hours? We advise tea drinkers to look also into the kettles used by their cooks. We never saw one not just brought from the store that was not crusted over at the bottom with a deposit of lime. Water out of such a utensil will not make a healthy cup of tea. If any one wishes to test this matter for himself let him have a little metal frame that will fit on any ordinary gas burner, leaving a flat surface at the top, on which to set a cup. If properly constructed (we have several in use) it will consume all the gas when lighted, will not smoke or smirch the cup placed over it, and (the sure test) will leave no odor whatever in the room to show that it is lighted. Take a common tin cup and pour into it a teacup and a half of pure cold water. Stir into this a teaspoonful of good English breakfast tea, and place the cup over the gas. The moment it comes to the boiling point pour it out through a silver strainer into a china teacup and season to the taste. That one experiment will show for all time to come how tea may be made. Regulate the strength by experience, as adding more tea to the infusion will only increase the tannin without drawing out any more theïne, and adding boiled water is almost certain to injure the flavor. A very important point to be observed, if tea is to serve as a wholesome, refreshing beverage is the method of drinking it. It should never be taken with food in alternate swallows according to a too prevalent custom. No liquid of this character should be taken with food. A horse or cow would die of indigestion if food and drink were administered to the animal as these are used by many people at their ordinary meals. First eat and then drink is the example set by the brute creation. A meal should always be served in courses, no matter how plain the table. Warm tea taken with food is less injurious than cold water, but it does retard the digestion and is always more or less hurtful. The great mistake made by Americans in their diet comes from the free use of diluents, especially at meal time. The ice water thus drank is an unmitigated curse. It kills annually far more people than die from the use of the alcoholic stimulants. A mouthful of food is chewed, mixed with saliva which the act produces, and is then swallowed. The stomach left to itself will take immediate care of it, turn it into a gray mixture suitable for home consumption and make it a vehicle of nourishment. But the eater cannot let well enough alone and on the top of his mouthful thus prepared he swallows a quantity of iced fluid from the goblet beside his plate. This chills the stomach at once, and the food taken with such an accompaniment will often lie as a load awaiting a revival of the digestive powers. A cup of hot tea, in which there is always more or less tannin, swallowed with the food, will also retard the digestion, although if properly made it is not as dangerous as the freezing water.

WOMEN'S WORK.

A NEW FIELD OF EFFORT AS SANITARY ENGINEERS.

A new career for women is suggested by the fact that a female sanitary engineer is now practising in London. She appears to be a lady of varied knowledge, as she has received certificates for music, art, hygiene, divinity, physiology, and sanitary science. She is a lecturer on domestic economy and hygiene at the Wordsworth College, London, and it is said gives learned discourses on the same subjects at the meetings of the National Health Society. This lady of versatile genius is Miss Scott, and she has been choosen to represent the women of England at the forthcoming International Congress of Hygiene, and will read a paper there. Miss Scott states: "I have visited slaughter houses, workshops, dairies, and all manner of places in order to get information, and have learned all that I possibly can about plumber's work. Of course I understand, too, all about the laying of drains, water mains, connections, and so on. I have had an application to examine and survey the drainage of a house in Hampstead. I expect I shall have to draw up a plan of the whole sanitary arrangements." There is nothing out of the way in women becoming sanitary engineers. When ability in this direction is applied to domestic sanitation, and women more generally become informed on the subject, the result will be more homes in a state of healthfulness. Women have made excellent inspectors, and their natural tendency towards cleanliness adapts them to sanitary work. Whatever a woman may find to do in a professional way with sanitary engineering, she can find a broad and inviting field for labor in securing the sanitation of her household.

ELECTRIC BOATS.—Electric pleasure boats are now in use in many places. Storage batteries are used in them, although the novelty is somewhat expensive.

FRUIT AND GOUT.—Recent researches in medicine show that persons having a tendency to gouty troubles generally improve more rapidly when they eat no fruit.

TELLING RESULTS.—The new sanitary measures adopted in England within the last few years, have reduced the number of deaths from consumption fully 30 per cent.

PIPE TEST.—To determine whether the joint of a sewer pipe leaks or not, wrap it with a piece of white cloth saturated with a solution of acetate of lead. If it leaks, the cloth will become black.

ALPINE OBSERVATORY.—The survey for an observatory upon Mount Blanc is now being made, and as soon as it is shown that iron columns can be sunk through the ice cap forming the summit, plans for the observatory will be prepared.

WRITING AND SPINE DISEASE.—In Austria it has been found that the slanting of letters in writing causes curvature of the spine, due to the position mainained at the table or desk, and a supreme council has recommended that upright letters be cultivated in schooling.

BRIGHT STORIES.

JENNY.

Translated from the French of Victor Hugo.

I.

It was night. The cabin, poor, but warm and cosey, was full of a half twilight, through which the objects of the interior were but dimly visible by the glimmer of the embers which flickered on the hearth and reddened the dark rafters overhead. The fisherman's nets were hanging on the wall. Some homely pots and pans twinkled on a rough shelf in the corner. Beside a great bed, with long, falling curtains, a mattress was extended on a couple of old benches, on which five little children were asleep like cherubs in a nest. By the bedside, with her forehead pressed against the counterpane, knelt the children's mother. She was alone. Outside the cabin the black ocean, dashed with stormy snow-flakes, moaned and murmured, and her husband was at sea. From his boyhood he had been a fisherman. His life, as one may say, had been a daily fight with the great waters; for every day the children must be fed, and every day, rain, wind, or tempest, out went his boat to fish. And while, in his four-sailed boat, he plied his solitary task at sea, his wife at home patched the old sails, mended the nets, looked to the hooks, or watched the little fire where the fish-soup was boiling. As soon as the five children were asleep, she fell upon her knees and prayed to Heaven for her husband in his struggle with the waves and darkness. And truly such a life as his was hard. The likeliest place for fish was a mere speck among the breakers, not more than twice as large as his own cabin—a spot obscure, capricious, changing on the moving desert, and yet which had to be discovered, in the fog and tempest of a winter night, by sheer skill and knowledge of the tides and winds. And there—while the gliding waves ran past like emerald serpents, and the gulf of darkness rolled and tossed, and the straining rigging groaned as if in terror—there, amidst the icy seas, he thought of his own Jenny; and Jenny, in her cottage, thought of him with tears.

She was thinking of him then and praying. The sea-gull's harsh and mocking cry distressed her, and the roaring of the billows on the reef alarmed her soul. But she was wrapped in thoughts—thoughts of their poverty. Their little children went barefooted winter and summer. Wheat bread they never ate, only bread of barley. Heavens! the wind roared like the bellows of a forge, and the sea-coast echoed like an anvil. She wept and trembled. Poor wives whose husbands are at sea! How terrible to say, "My dear ones—father, lover, brothers, sons—are in the tempest!" But Jenny was still more unhappy. Her husband was alone—alone without assistance on this bitter night. Her children were too little to assist him. Poor mother! Now she says, "I wish they were grown up to help their father!" Foolish dream! In years to come, when they are with their father in the tempest, she will say with tears, "I wish they were but children still!"

II.

Jenny took her lantern and her cloak. "It is time," she said to herself, "to see whether he is coming back, whether the sea is calmer, and whether the light is burning on the signal mast." She went out. There was nothing to be seen—barely a streak of white on the horizon. It was raining—the dark, cold rain of early morning. No cabin window showed a gleam of light.

All at once, while peering round her, her eyes perceived a tumble-down old cabin which showed no sign of light or fire. The door was swinging in the wind, the worm-eaten walls seemed scarcely able to support the crazy roof, on which the wind shook the yellow, filthy tufts of rotten thatch.

"Stay," she cried, "I am forgetting the poor widow whom my husband found the other day alone and ill. I must see how she is getting on."

She knocked at the door and listened. No one answered. Jenny shivered in the cold sea-wind.

"She is ill. And her poor children! She has only two of them; but she is very poor, and has no husband."

She knocked again, and called out, "Hey, neighbor!" But the cabin was still silent.

"Heaven!" she said, "how sound she sleeps, that it requires so much to wake her!"

At the instant the door opened of itself. She entered. Her lantern illumined the interior of the dark and silent cabin, and showed her the water falling from the ceiling as through the openings of a sieve. At the end of the room an awful form was lying—a woman stretched out motionless, with bare feet and sightless eyes. Her cold white arm hung down among the straw of the pallet. She was dead. Once a strong and happy mother, she was now only the spectre which remains of poor humanity, after a long struggle with the world.

Near the bed on which the mother lay, two little children—a boy and a girl—slept together in their cradle, and were smiling in their dreams. Their mother, when she felt that she was dying, had laid her cloak across their feet and wrapped them in her dress, to keep them warm when she herself was cold.

How sound they slept in their old, tottering cradle, with their calm breath and quiet little faces! It seemed as if nothing could awake these sleeping orphans. Outside the rain beat down in floods, and the sea gave forth a sound like an alarm-bell. From the old creviced roof, through which blew the gale, a drop of water fell on the dead face, and ran down it like a tear.

III.

What had Jenny been about in the dead woman's house? What was she carrying off beneath her cloak? Why was her heart beating? Why did she hasten with such trembling steps to her own cabin, without daring to look back? What did she hide in her own bed, behind the curtain? What had she been stealing?

When she entered the cabin the cliffs were growing white. She sank upon the chair beside the bed. She was very pale; it seemed as if she felt repentance. Her forehead fell upon the pillow, and at intervals, with broken words, she murmured to herself, while outside the cabin moaned the savage sea.

"My poor man! Oh, heavens, what will he say? He has already so much trouble. What have I done now? Five children on our hands already! Their father toils and toils, and yet, as if he had not care enough already, I must give him this care more. Is that he? No, nothing. I have done wrong—he would do quite right to beat me. Is that he? No! So much the better! The door moves as if some one were coming in; but no. To think that I should feel afraid to see him enter!"

Then she remained absorbed in thought, and shivering with the cold, unconscious of all outward sounds, of the black cormorants which passed shrieking, and of the rage of wind and sea.

All at once the door flew open, a streak of the white light of morning entered, and the fisherman, dragging his dripping net, appeared upon the threshold, and cried, with a gay laugh, "Here comes the Navy!"

"You!" cried Jenny; and she clasped her husband like a lover, and pressed her mouth against his rough jacket.

"Here I am, wife," he said, showing in the firelight the good-natured and contented face which Jenny loved so well.

"I have been unlucky," he continued.

"What kind of weather have you had?"

"Dreadful!"

"And the fishing?"

"Bad. But never mind. I have you in my arms again and I am satisfied. I have caught nothing at all. I have only torn my net. The deuce was in the wind to-night. At one moment of the tempest I thought the boat was foundering, and the cable broke. But what have you been doing all this time?"

Jenny felt a shiver in the darkness.

"I?" she said, in trouble. "Oh, nothing; just as usual. I have been sewing. I have been listening to the thunder of the sea, and I was frightened."

"Yes, the winter is a hard time. But never mind it now."

Then, trembling as if she were going to commit a crime:

"Husband," she said, "our neighbor is dead. She must have died last night, soon after you went out. She has left two little children, one called Wilhelm and the other Madeline. The boy can hardly toddle, and the girl can only lisp. The poor, good woman was in dreadful want."

The man looked grave. Throwing into a corner his fur cap, sodden by the tempest: "The deuce!" he said, scratching his head. "We already have five children; this makes seven. And already in bad weather we have to go without our supper. What shall we do now? Bah, it is not my fault; it's God's doing. These are things too deep for me. Why has He taken away their mother from these mites? These matters are too difficult to understand. One has to be a scholar to see through them. Such tiny scraps of children! Wife, go and fetch them. If they are awake, they must be frightened to be alone with their dead mother. We will bring them up with ours. They will be brother and sister to our five. When God sees that we have to feed this little girl and boy besides our own, He will let us take more fish. As for me, I will drink water. I will work twice as hard. Enough! Be off and bring them! But what is the matter? Does it vex you? You are generally quicker than this."

His wife drew back the curtain.

"Look!" she said.

FOOD FANCIES.

SOME SAVORY SUGGESTIONS FROM A BRITISH CONTEMPORARY.

The French make great use of lettuce as a vegetable, and a most excellent vegetable it is, cooked either *a la creme* or *au jus*.

A plain and easy way of cooking new-laid eggs for breakfast is to steam them during four minutes in a potato steamer.

The Blenheim is the best all-round apple grown in this country. It makes a perfect dish cooked without sugar, and that, we take it, is the highest test for an apple.

The vol-au-vent, or fly-in-the-wind pie, is the lightest sort of pastry known to French cooks, and is filled with mushrooms and other appetizing dainties swimming in a rich sauce.

Bananas peeled, cut into long slices, fried in butter and laid on a hot dish, and garnished with eggs also fried in the same butter, constitute a particularly nice entrée for a light dinner or luncheon.

A correspondent of *Rod and Gun* reports a culinary experiment of some interest. A couple of adult otters were captured at Killaloe, and the tails converted into a soup, which was found to be quite as palatable as any oxtail soup.

So-called "roast" meat cooked in ovens is a delusion and a snare. Roast meat is roast meat, and in order to roast you must have an open fire, before which your joint is placed in such a manner that the air circulates freely around it.

The best frying bath is one composed of beef suet and veal fat in equal proportions, melted down; the grease of the dripping-pan and of the pot-au-feu is also good; lard, too, may be used, although it leaves the surface of the fried food less pure.

An exquisite cold hors d'œuvre are fresh figs, served at the beginning of the repast. In Southern Europe one gets this hors d'œuvre in perfection. Anywhere around the Bay of Naples a dish of figs, a slice of smoked ham, and a flask of red wine make a delicious meal.

The last new sandwich is composed of chopped celery and powdered Parmesan cheese, with an infinitesimal addition of cayenne pepper. This preparation may be laid between thin slices of either white or brown bread and butter. It would answer equally well as a savory.

It is not generally known that eggs can be easily flavored to suit the taste. They at once absorb any fragrance or odor with which they are placed in contact, and by storing the eggs in a basket lined with roses or violets they will shortly be found to have acquired the flavor of the flowers.

In cooking cauliflower, asparagus, string beans, and any other vegetable which may sometimes have a slightly bitter taste, due to accidents of culture or what not, it is well always to put a lump of loaf sugar into the water. This precaution will effectually counteract the bitterness, if there be any.

Cookery books generally recommend the use of a beaten egg to make the flour, bread crumbs, or chopelure adhere to a sole, for instance, which is to be fried. A simpler method is to dip the sole in milk and then roll it in your flour; thus you avoid the thick lumps and patches of crust which are almost inevitable when an egg is used.

In the matter of sandwiches, it is now difficult to find a novelty. The following little snack made its first appearance at a recent reception of a well known leader of fashion. It looked like a roll of brown bread and butter, but further investigation showed that it was a sort of pate formed of brown bread, ham and chicken—these three things pounded together, and then moulded as you do quenelles. So made, sandwiches are appetizing and worth experimenting with in public bars, although rather expensive.—*London Caterer.*

CURRANTS OR CORINTHS?

CORNER GROCERY WISDOM EMITTED THROUGH A REPORTER.

"Mother wants a pound of dried currants," said a little girl who came into the learned grocer's store on Eighth avenue. "I hain't got a dried currant in the store, and there hain't one in the city," replied the grocer. "But I know what you want, and I've got 'em." The learned grocer brought forth a box of the little sticky, sugary, dried fruit popularly known as dried currants, and used in fruit cake, plum puddings, mince pies, buns, and the like. "Why, them's 'em!" said the little girl. "Yes, them's 'em," assented the grocer; "and if the Grecian maiden who trod this particular lot of fruit into the package had used a little water on her feet before she began, there wouldn't be so much sand and grit in 'em as there is. She must have been having a regular hoe-down on the classic sands before she began to dance on this box of fruit. There, sissy, tell your mother she must bathe 'em in several waters before she uses 'em, or she might just as well put a lot of sand-paper in her fruit cake. And tell her they ain't dried currants, either." "What's the reason they ain't dried currants?" asked a disputative customer. "They ain't dried currants any more than they're dried pumpkins!" replied the grocer. "The reason they ain't dried currants is that they weren't currants before they were dried. That's reason enough, ain't it?" "Yes," said the customer, less disputative. "But what does everybody call 'em dried currants for?" "'Cause they don't know any better," replied the grocer. They'll go right on coming in here and asking for dried currants just the same after I tell 'em why they ain't dried currants as they did before." "What should they ask for, then?" inquired the customer. "If any man should come in here and ask for dried corinths," said the grocer, "he would not necessarily be a gentleman, but I'd bet on him for being a scholar. Dried corinths is what you should ask for when you want this little sugar-coated, gritty raisin, for it's a raisin, pure and simple." "How's that?" the customer wanted to know. "Because it was a grape before it was dried," said the grocer, "and if dried grapes ain't raisins what are they?" "But you said these were dried corinths!" said the customer. "What's a corinth, anyhow?" "A corinth is the smallest grape that grows," replied the grocer, "and it lost its name years and years ago, because it was gradually corrupted into currant, which became the name of the acidulated little berry of our garden, which you might dry from now until Gabriel sounds his horn without getting it any nearer the condition of a raisin than a pea is. This little grape grows all over the islands of the Grecian archipelago, and was first exported from Corinth, and that's what gave it its name. The bunches don't grow much bigger than a stem of red currants, and they are so full of sugar that when they are picked and dried in the sun they actually seem to melt and run together, and it takes a good deal of care and labor to separate them again. After they are separated is the time that the Grecian maiden gets her work in on them, for it is one of her pleasant duties to jump on a heap of the sticky fruit with her bare feet until she has compressed enough of the little raisins to pile three boxes into one. No hydraulic press could do it any better. If it could, we wouldn't have the sand and grit the maidens' feet mingled with the fruit, without which no dried corinths are genuine. Still I shall expect folks to come in here and ask for dried currants just the same," said the learned grocer, as he went to wait on a new customer.—*Sun.*

DOMESTIC DIETETICS.

SPECIALLY PREPARED, FROM PRACTICAL TESTS, FOR THE LADY READERS OF THE "AMERICAN ANALYST."

SEASONABLE FOOD.

August.

GAME AND POULTRY.—Pigeon, chicken, duck, woodcock.

MEAT.—Beef, lamb, mutton, ham, kidneys, liver, sausage, veal, venison.

FRUITS.—Cherries, raspberries, huckleberries, melons, gooseberries, blackberries, peaches, pears, tamarinds, bananas, pineapple, grapes, plums.

FISH.—Anchovy, bass, bluefish, blackfish, cod, eels, crabs, clams, flounders, halibut, herrings, lobster, mackerel, mussels, porgie, prawn, salmon, turtle, trout, sturgeon, whiting, weakfish, rockfish.

VEGETABLES.—Beans, beets, cucumbers, cabbage, carrots, cauliflower, corn, egg-plant, lettuce, onions, parsley, parsnips, potatoes, squash, shallots, spinach, turnips, radish, rhubarb, tomatoes.

PRACTICAL RECIPES.

MULLIGATAWNY SOUP.—Select a good sized fowl and cut it in pieces and break the bones; take a piece of the chicken fat and put it in the soup pot, and when melted add some soup vegetables cut fine and let them cook for a few minutes; then add a couple of pounds of veal cut into small pieces and cook a quarter of an hour longer, then put in the chicken and six quarts of water and let it boil up once, then skim and set back to cook slowly for four hours. Put three table-spoonfuls butter in a pan and when melted add four tablespoonfuls of flour and cook until the flour is brown, then take off the fire and add a tablespoonful of curry powder. Strain the soup, return it to the kettle and add this mixture; cook for a few minutes, then add pieces of the chicken cut into dice; cook for a half hour, then serve.

DRY CURRY OF MUTTON.—Cut the cold boiled mutton into neat sized pieces and make slight incisions in the meat; rub the curry in these, then sautè the meat in a little butter until thoroughly heated.

HAM TOAST.—Put a table-spoonful of butter in a sauce pan, when melted add to it half a cup of cream and the well beaten yolks of two eggs; boil up, stirring well, and add a cup of finely minced cold boiled ham, a little onion juice, and seasoning to taste. Lay some slices of thin toast on a hot platter, pour some of the ham on each and serve.

A CREAM CAKE.—Make a fine five egg cup cake and bake it in a round mould. When done and cold cut off the top of it and scoop out the insides to within a couple of inches of the crust; crumble up the insides of the cake and add to the crumbs a rich custard, made with three eggs to a pint of milk, sweetened and flavored with vanilla, nutmeg and a very little salt; also add a couple of spoonfuls of raspberry jam. Beat these together and fill up the cake with the mixture. Pile whipped cream on top and serve very cold.

SKELETON POTATOES.—Pare some rather long potatoes and with a very sharp knife cut them round and round in spirals, but do not break them. Dry them, and fry in boiling lard; take out, drain, sprinkle with salt and serve.

HORSERADISH SAUCE FOR FISH.—Heat a pint of cream and season it with pepper, salt, and four ounces of horseradish. Pour into a tureen and serve.

LOBSTER BUTTER.—Pound some cooked lobster spawn with the coral of the lobster and some butter until it will go through a hair sieve; season, and serve with fish.

FRIED SALSIFY.—Boil it in water, cut it into short sticks, drain, and let it soak for an hour in vinegar, with salt and pepper. Dip the sticks into a thin batter, fry quickly in dripping, and serve.

BERLIN DOCTORS.—Berlin gives the carriages of physicians the right of way through the crowded streets. The coachmen wear a distinctive white hat.

BECOMING COMMON.—Onyx is in danger of losing its special value. Besides the great deposits discovered in Missouri extensive layers have been found in Smyth County, Virginia.

BRIDGE BUILDING.—The law of the Unted States is that bridges over navigable streams must be built under the sanction of the War Department. The law is to be more vigorously enforced than formerly.

FRANK AND COURTEOUS.—In last week's issue we published under the head "Domestic Dietetics" specially prepared for the *True Democrat;* also "Seasonable Food for July," and several "Practical Recipes." These were clippings from the AMERICAN ANALYST, and that valuable paper should have had the credit. It says so, and I think so too.—Editor *Balt. True Democrat*, July 18.

A NATURAL THERMOMETER.—Anxious mother—"I wish, Susan, when you give baby a bath you would use the thermometer so as to ascertain whether the water is at the proper temperature."

Susan—"Oh, don't you worrit about that, mum; I nade no 'mometers. If the little wan turns rid, the wather's too hot; if it turns blue, it's too could; that's all there is about it."

MRS. ASTOR'S JEWELS.—Mrs. William Astor has a wonderful snake ring which literally writhes in constant motion on her finger. It is constructed of flexible gold wire, each scale being represented by a loop of wire in which a ruby, an emerald or an amethyst is firmly set. The slightest movement of the fingers sets the wire a-quiver, and the ring scintillates and seems to go round and round the finger with a serpentine movement that has something eerie in it. It was made in Egypt. The same lady has a marvelous necklace, composed of six strings of magnificent diamonds, all the stones being invisibly set, so that they look as though they were simply strung together like beads.

LA MANHATTIENNE.

WHY THE NEW YORK GIRL IS THE MOST CHARMING GIRL IN CREATION.

The most predominant characteristic of the New York girl is that she is always there. If it is a new book, she has read it. If it is a new play, she has seen it. If it is a new style of gown, she has it on, and if it is the last new man to whom she has been introduced, he is pleading for an invitation to call on her. She is healthy, because she believes in bathing and plenty of exercise. Her eyes are clear; and if she walks a little too rapidly for absolute grace, you know it is because she has an object in view, and she intends to gain it. She is slightly cynical. She has by no means an abiding faith in men, and she believes that "out of sight out of mind" is usually true as applied to them; consequently she meets them on their own ground, and in her close-fitting tailor-made suit, leaves them victims on the field of coquetry, slain by a determined enemy, and with weapons they don't exactly understand. She is nothing if not good form. She must have a frock fit and fit well, whether it be calico or brocade; but above everything else she puts her faith in the tailor-made frock. The figure of which she is so proud shows well in it, and her trim, well groomed air demands it. She thinks the New England girl tiresome, the western one breezy, and the southern one "a sweet little thing." She cannot understand why women are afraid to cross the street alone, nor why she should be ashamed to go in and get some luncheon and tip the waiter well. She thinks that southern men are magnificent, that western ones swirl one along, and the New England ones are well enough to marry, if they have got money, but are not to be considered unless they have. She belongs to three or four classes, usually speaks French well, and is probably a good performer on the mandolin or banjo. She is straightforward, and yet she fully understands that language was invented to conceal one's thoughts. Her manners are irreproachable. Imitating her English cousin, she has subdued her voice a little, and if she attempts the English drawl she does it in a way rather fascinating. She is interested in no end of charities, and works well for them. She reads most of the novels, a great deal of the poetry, and has an opinion on every subject, from Tolstoi to the best way to mend the thumb of a glove. Take her for all in all she is extremely interesting; she has enough knowledge of the world not to make mistakes when she is in it and of it, and she is enough a true-hearted girl to love her own people, her friends, and to be sympathetic with those who are in sorrow. If she has a fault—and I like her so much that I doubt it—it is that she is a little too sure. She never questions her ability to succeed. She has a bright way of saying "good morning," and an equally bright one of bidding one "good night." The New York girl is a creature not too bright or good, but essentially a clever girl, who has gleaned knowledge from all over the world, and who knows how to use it to the best advantage. Can you ask anything more?—*Ladies' Home Journal.*

PERSPIRATION AND TRANSPIRATION.

If the skin be examined with a powerful magnifying glass it has the appearance of a great sieve whose apertures are of all shapes and sizes. Some are moist from water that slowly oozes outward to the surface. This water, when evaporated on a watch crystal leaves little crystals of salt and ammoniacal compounds. Dried on blotting paper or woven tissue, and left in a close place, it undergoes fermentation and putrefaction, emitting an unpleasant odor. These show that the pure liquid has been used by nature to relieve if not cleanse the blood, to cool off the system, to soften the skin, to force off the dead cuticle, and probably to wash the exterior tissues of the body. In a second class of apertures there is a pale yellowish oil. Sometimes there is more stearine and less oleomargarine in the oil than there should be, and it then becomes almost solid. If dust gets in it is held by the fat, which becomes yellow, brown, and then black. It is then said to be a blackhead. If the grease is too hard, local inflammation sets up, and a pimple or boil results, according to the size of the sac which contains it. Sometimes the outlet to the sac is closed and the inflammation, unable to expel the grease induces the system to reabsorb it. This is a dry pimple, and when superinduced by the excessive use of alcoholic stimulants is appropriately termed a toddy blossom. The oil answers many purposes. It keeps the skin and tissues soft, pliable and smooth; in many cases it acts as a lubricant, and what is too often overlooked by people, it carries with it away from the skin the fine dust always depositing from the air. In addition to these two classes of apertures there is a third, which sometimes seems as an outlet for perspiration, but usually is what may be called an air outlet. These pores act as the escape valves of much larger amounts of gas than is usually supposed. Even when they seem to be filled with perspiration this liquid is full of bubbles, showing that two processes are going on at the same time. In health this complex system is forever at work unnoticed and almost unknown. Its normal activity means strength, comfort and beauty. Increased exertion causes an increase in transpiration, and this in turn relieves the lungs and the heart, and also reduces the temperature, which has been raised above the normal. In ill health all this is changed. In some cases where there is much vitality the skin is reddened and eruptions appear on the body; in others, pimples, boils and abscesses make their appearance, and inflict excruciating agony; in still others there are cold sweats, shivers, fevers and a clammy moist skin, and in others again there comes into being that hideous pallor and bloodlessness which too often indicate deep seated disease, years of intense suffering, and a lingering, painful death. Too much care cannot be taken of the skin in order to avert many of these evils. The body should be bathed in lukewarm water at least twice a week, and then rubbed with a soft towel until it is in a warm glow. So much for the external treat-

Buffalo Lithia Water, Spring No. 2, in Bright's Disease, Gout, Stone in the Bladder, and Diseases Generally of Uric Acid Diathesis, Etc., Etc.

DR. WM. A. HAMMOND, of Washington, D. C., Surgeon General U. S. Army (retired), Professor of Diseases of the Mind and Nervous System in the University of New York, etc.

"I have for some time made use of the BUFFALO LITHIA WATER in cases of AFFECTIONS of the NERVOUS SYSTEM, complicated with BRIGHT'S DISEASE OF THE KIDNEYS or with a GOUTY DIATHESIS. *The results have been eminently satisfactory.* Lithia has for many years *been a favorite with me in like cases, but the* BUFFALO WATER CERTAINLY ACTS BETTER THAN ANY EXTEMPORANEOUS SOLUTION of THE LITHIA SALTS, and is, moreover, better borne by the stomach. I also often prescribe it in those cases of CEREBRAL HYPERÆMIA resulting from OVER MENTAL WORK—in which the condition called NERVOUS DYSPEPSIA exists—*and generally with* MARKED BENEFIT."

DR. WM. B. TOWLES, Professor of Anatomy and Materia Medica, in the Medical Department of the University of Virginia.

"BUFFALO LITHIA SPRINGS, No. 2, belongs to the ALKALINE or, *perhaps, to the* ALKALINE SALINE Class, *for it has proved far more efficacious in many diseased conditions than any of the simple* ALKALINE waters.

"*I feel no hesitancy whatever in saying that in* GOUT, RHEUMATIC GOUT, RHEUMATISM, STONE *in the* BLADDER, and in all diseases of URIC ACID DIATHESIS, *I know of no remedy at all comparable to it.*

"*Its effects are marked in causing a disappearance of* ALBUMEN *from the urine. In a* single case of BRIGHT'S DISEASE *of the* KIDNEYS, I witnessed *decided beneficial results from its use, and from its action in this case I should have great confidence in it as a remedy in certain stages of this disease.* In DYSPEPSIA, especially that form of it in which there *is an excessive production of* ACID *during the process of nutrition*, in some of the PECULIAR AFFECTIONS *of* WOMEN, notably in SUPPRESSION of the MENSES, and in CHRONIC MALARIAL POISONING, etc., I have found it highly efficacious."

DR. G. HALSTEAD BOYLAND, late Professor of Surgery, Baltimore Medical College, late Surgeon French Army (Decorated), Member Baltimore Academy of Medicine, Member of American Medical Association.

"In BRIGHT'S DISEASE of the KIDNEYS, ACUTE or CHRONIC, BUFFALO LITHIA WATER, Spring No. 2, is, in my experience, *without a rival*, whether in the PARENCHYMATOUS form or INTERSTITIAL NEPHRITIS. In cases in which the ALBUMEN in the URINE reached as high as 50 per cent., I have known it under a course of this water gradually diminish and finally disappear, at the same time other alarming symptoms were relieved and the sufferers restored to health.

"In STONE in the BLADDER of the RED LITHIC ACID and the WHITE PHOSPHATIC DEPOSIT, the SOLVENT power of this water is *unmistakable.*"

Water in cases of one dozen half gallon bottles, $5.00 f. o. b. here.

THOS. F. GOODE, Proprietor, BUFFALO LITHIA SPRINGS, VA.

ment. The internal is equally simple, and consists in keeping the bowels open, and stimulating the vital organs by the use of Ayer's Sarsaparilla. This superb compound acts upon the skin by influencing all the forces that control it. It purifies the blood, and so prevents the deposition of the coloring matter, which is so familar in the faces of those who are sallow, grayish, anemic or pimply. It regulates the liver, and so puts an end to the discloration produced by bile, which finds its highest development in jaundice. It acts as a tonic upon the secondary nervous system, and so strengthens those involuntary processes in which the skin plays so large a part. It assists the intestines, and thus remedies constipation on the one side, and dysenteric troubles on the other. In this way it frees the system from all humors and restores it to a perfect condition. With Ayer's Sarsaparilla, accompanied by compliance with the principles mentioned, perspiration and transpiration become normal, and health, strength and a beautiful complexion are the sure results.

Subscription $1.00 per year. Now is the time to subscribe.

Pure is one thing; wholesome, another. Pure arsenic is not wholesome. Pure ammonia, pure white clay, or pure alum cannot make a wholesome baking powder, even if it is called "absolutely pure."

Every housekeeper knows that pure cream of tartar, pure soda, pure flour, are wholesome. These three ingredients, and these three only, are used in Cleveland's Baking Powder. Cleveland's is pure *and* wholesome; it leavens most, and leavens best, but its special excellence is that it is perfectly wholesome.

On the Ragged Edge

—The clothes that are washed without *Pearline*. If you get them clean by the necessary rubbing with soap, they will soon get ruined by the wear of it.

Pearline saves the wear, by saving the work—there is little or no rubbing. It does no harm to anything. Use *Pearline*, and use less labor. Labor is useless, if you use *Pearline*, for it is unnecessary.

The Edge of despair. The peddlers and prize givers must be there, lest why should they use such methods and claim their goods "the same as," or "as good as" Pearline. IT'S FALSE—Pearline has no equal and is never peddled.

240 JAMES PYLE, New York

BUSINESS NOTES.

FOR SLEEPLESSNESS

Use Horsford's Acid Phosphate. Dr. C. R. Dake, Belleville, Ill., says: "I have found it, and it alone, to be capable of producing a sweet and natural sleep in cases of insomnia from overwork of the brain, which so often occurs in active professional and business men."

CHEERFULNESS DESIRABLE.—Every one knows the advantage of a good bedside manner to the physician. In his chatty address to the students at University College, Sir Edward Quain told how its need was impressed upon him at an early stage of his career. When quite a young man he was placed in temporary charge of a patient, and full of the weight of his unaccustomed responsibility, his countenance grew longer and longer. When he was leaving one day the lady's husband followed him. "I greatly appreciate the anxiety you feel for my poor wife," he whispered, "but please don't let her see it again, for after you had left the room she asked me if you were the undertaker."

INGENIOUS THERMOMETER.—A very sensitive metallic thermometer, with electrical recording apparatus, has been devised by a French mathematician. The thermometer proper consists of a bar of metal firmly fixed at one end, and at the other end joined to a short arm of a lever, the long arm of this lever being attached to another bar. A second bar, connected at its other extremity with a similar lever, operates a pointer working on a dial, which registers in degrees the expansion of the two bars. By suitable electrical attachments the temperature is recorded at any distant point, no matter what the distance. This device is of great value where a constant heat must be maintained in a manufacturing establishment, as the recording of the temperature may be read in the office.

FORESTS AND BACTERIA.—Investigations have been made by Serafini and Arata to determine the correctness of the belief that the foliage of trees has some influence in filtering out the bacterial contents of the atmosphere. Their method of procedure was to determine the number of bacteria in air under motion before and after it had reached the woods. The barometrical pressure, direction and strengh of the wind, temperature at the edge and in the midst of the woods, humidity and rainfall, were all taken into consideration. As the number of observations were only 40, the investigators give the results with some reserve, nevertheless they believe that they are justified in affirming that forests do exercise the power of straining out the bacteria that are brought to them by the wind.

THE "TIP" FRAUD.—Brussels, at the time of writing, is threatened with a strike of waiters. It is novel in this respect, that it may be described as a strike against "tips." Whether the Belgian public is more generous than other publics, or not, we are not aware; but it seems certain that the proprietors of Brussels restaurants and taverns are more wily than others. In the first place, they make their waiters spend the early morning in cleaning the establishment in which they serve, and then they demand of the unfortunate men from 1½f. to 6f., according to the class of establishment, out of the *pour-boires* given to the waiters by the customers, and which constitute the sole emolument of the former. Hitherto the public does not seem to have been aware that, by giving the obligatory *pour-boire*, they have really benefited the proprietors rather than the hard-worked waiters. The latter in self-defence, now suggest the entire suppression of the *pour-boire*, and the substitution of a fixed salary. The demand seems not only a just, but an eminently business-like, one, for the system of payment by "tips" is never really satisfactory or advantageous to anybody.

WATCHES.

EVERY one wants a watch, and naturally a good watch that keeps accurate time, presents a handsome appearance, and is inexpensive. If such a watch can be found of American manufacture, it is an additional appeal to our patriotism. Just such a watch as this ideal THE ANALYST PUBLISHING COMPANY is enabled to offer as a Premium to its readers. Having some large advertising contracts we have been enabled to procure the movements of the manufacture of the best known American watch factories, namely, the Waltham, Elgin, Hampden and Illinois Watch Companies. These movements are adapted for both ladies' and gentlemen's watches, and are warranted by the makers. These movements have seven jewels, patent lever movement, chronometer balance, patent safety pinion, sunk hard-enameled dial, straight line visible palette, stem winders, hand set; in fact, contain all the latest improvements and can be readily cleaned or repaired by any ordinary good watchmaker. They can be regulated to run as close as any movement.

It is needless to say that to case these movements in solid gold cases would make them too expensive, yet they are cased in what are known as gold filled or stiffened "Ladd" cases, and are warranted to be 14 karat gold, made from two sheets of 14 karat gold overlaying fine composition metal, with regular jointed caps, covers and bezels, and to wear at least five years. They are not plated, nor rolled gold, but actual 14 karat gold cases, thin of course, but stiffened and strengthened by being filled with this fine composition metal. They are finished in the same manner, engine turned and engraved as solid gold watches, and wear and look just the same. No one but an expert can tell them from a solid gold watch. These watches are made both open face and hunting case style, in gentlemen's or ladies' sizes. For gentlemen we recommend plain engine-turned cases; for ladies, a handsomely engraved case.

How to Obtain One of these Watches.

These watches are not to be purchased from us at any price. Send us a club of 25 subscribers to the AMERICAN ANALYST, and $25, the regular subscription price, and one of these watches (your choice of style and size) will be immediately forwarded, post-paid and registered, to your address. You need not wait until you have your 25 subscribers all together, but forward them as you get them and they will be credited to you, and when the number is complete the watch will be sent. A subscription for two or three years will be counted as two or three subscribers.

As these watches are retailed by jewelers at not less than $25, it will be seen that we are offering a real premium with the sole object of increasing our circulation, and that by taking advantage of our offer any one can obtain a good, reliable and handsome watch without cost. As the number of these watches at this price is limited, it is advisable to take steps at once to procure a bargain.

THE ANALYST PUBLISHING CO., 19 PARK PLACE, NEW YORK.

BICYCLES

GIVEN AWAY TO BOYS AND GIRLS!

AN OPPORTUNITY OPEN TO ALL.

The Analyst Publishing Company being desirous of largely increasing their subscription list, will furnish every one with a beautiful Safety Bicycle, ABSOLUTELY FREE, in return for a few hours' canvassing.

To every boy and girl who secures 75 subscribers for the American Analyst at $75, we will give a splendid

$40.00

NONPAREIL

SAFETY BICYCLE.

These bicycles are adapted in size to boys, but are strong enough to carry a man. A boy's bicycle should be a strong one. They are manufactured by the OVERMAN WHEEL CO., the makers of the celebrated VICTOR Bicycle, and have the full guarantee of the makers.

The following is a brief description of the NONPAREIL SAFETY; 26-inch wheels; ball bearing all around, including pedals; solid crescent rims; double tangent spokes; three-fourths inch tires; cranks, three throw, $4\frac{1}{4}$ to $5\frac{3}{8}$ inches; guards to both wheels; tool-bag, oiler and wrench. Finished in bright enamel, all exposed metal heavy nickel-plate on copper.

In selecting these machines as a premium, we have disregarded cheapness and selected a Bicycle which is serviceable, and the makers of which have an established reputation for building the best Bicycle that money, machinery and brains can produce. We are actually furnishing the Bicycles and Papers at less than cost, but hope by stimulating active and successful canvassing, and thus enlarging our subscription lists, to make an eventual profit. We positively guarantee these bicycles to be just as here represented. They will be shipped by express f. o. b. in New York.

Subscription orders must be made out plainly and legibly, and sent as fast as secured, addressed to

THE ANALYST PUBLISHING CO., 19 Park Place, New York.

TABASCO PEPPER SAUCE;

OR LIQUID PEPPER.

Is simply the Pulp of the Ripe Pepper Extracted by Pressure.

The seed of this Pepper was obtained from Central America, and by careful cultivation in Louisiana for many years has been so improved in strength, flavor and aroma, as to have become a new variety of Red Pepper, superior to all others. The pulp is so handled as to retain all the flavor, strength, aroma and color of the ripe fruit, and to keep unimpaired in any climate. It excites the appetite, promotes digestion, and is pronounced by connoisseurs to be the finest condiment in the world. For medicinal purposes it recommends itself by its purity, strength and diffusible form.

WHAT A DIME WILL DO!

Every BOY and GIRL who loves to read splendid Stories, Sketches and beautiful Poems, should subscribe for the AMERICAN YOUNG FOLKS, a beautiful Illustrated Monthly Magazine, established in 1875. Its stories are the Very Best that can be obtained from the Foremost Writers of Juvenile Literature, and every issue is filled with good things. The regular subscription price is $1.00 a year, but if you will **Cut this out** and return it to us with **a Silver Dime** and your name and address, we will send you the Magazine Six Months on Trial. Address,
AMERICAN YOUNG FOLKS, Manchester, N. H.

THE ORIGINAL AND GENUINE
(WORCESTERSHIRE SAUCE).
LEA & PERRINS' SAUCE

In consequence of Imitations calculated to deceive, we call attention to the fact that each bottle of the Original and Genuine WORCESTERSHIRE SAUCE, bears our signature thus—
Lea & Perrins
Beware of Imitations; see that you get Lea & Perrins'
For sale in Bottles only (not in bulk), by Dealers in Sauces throughout the World.
JOHN DUNCAN'S SONS, NEW YORK.

DO YOU KNOW THE **DANGER** OF USING SOAP?

IF YOU ARE GOING TO THE COUNTRY, DO NOT FAIL TO READ THE FOLLOWING.

We do not mean soap made from proper material; and when we tell you that about ninety-nine per cent. of Toilet Soap is made from refuse fats gathered from tenement houses, hospitals, butcher shops, and from cattle dying of disease or during transportation, you will, we believe stop and think. Putrefactive changes have taken place in most of this material, as it is mixed with lean meat, blood, bones, sinews, etc. There is at least *one* soap that is made wholly from vegetable material—OLIVE and PALM OILS—and that is

VELVET SKIN SOAP.

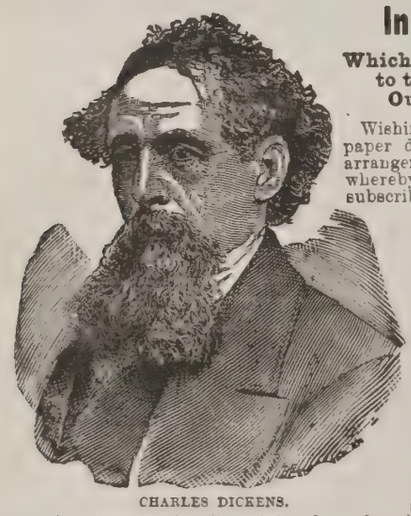
It will keep the skin soft and in a healthy condition, as no animal fats are used in its manufacture. Nothing in one's personal outfit is quite so satisfactory as a thoroughly reliable Toilet Soap.

We are confident that a trial of this article will insure its continued use. If the dealer does not keep it, do not take any other, but require him to order it for you, which he can do readily. **Otherwise, send to us direct.**

MANUFACTURED BY

REED & CARNRICK, Manufacturing Chemists,

447 GREENWICH STREET, NEW YORK.



GRAND PREMIUM OFFER!

A SET OF THE

WORKS OF CHARLES DICKENS,

In Twelve Large Volumes,

Which we Offer with a Year's Subscription to this Paper for a Trifle More than Our Regular Subscription Price.

CHARLES DICKENS.

Wishing to largely increase the circulation of this paper during the next six months, we have made arrangements with a New York publishing house whereby we are enabled to offer as a premium to our subscribers a **Set of the Works of Charles Dickens, in Twelve Large and Handsome Volumes,** with a year's subscription to this paper, for a trifle more than our regular subscription price. Our great offer to subscribers eclipses any ever heretofore made. Charles Dickens was the greatest novelist who ever lived. No author before or since his time has won the fame that he achieved, and his works are even more popular to-day than during his lifetime. They abound in wit, humor, pathos, masterly delineation of character, vivid descriptions of places and incidents, thrilling and skillfully wrought plots. Each book is intensely interesting. No home should be without a set of these great and remarkable works. Not to have read them is to be far behind the age in which we live. The set of Dickens' works which we offer as a premium to our subscribers is handsomely printed from entirely new plates, with new type. The twelve volumes contain the following world-famous works, each one of which is published *complete, unchanged, and absolutely unabridged:*

DAVID COPPERFIELD,
MARTIN CHUZZLEWIT,
NICHOLAS NICKELBY,
DOMBEY AND SON,
BLEAK HOUSE,
LITTLE DORRIT,
OUR MUTUAL FRIEND,
PICKWICK PAPERS,
BARNABY RUDGE AND CHRISTMAS STORIES,
OLIVER TWIST AND GREAT EXPECTATIONS,
THE OLD CURIOSITY SHOP AND THE UNCOMMERCIAL TRAVELER,
A TALE OF TWO CITIES, HARD TIMES AND THE MYSTERY OF EDWIN DROOD.

The above are without question the most famous novels that were ever written. For a quarter of a century they have been celebrated in every nook and corner of the civilized world. Yet there are thousands of homes in America not yet supplied with a set of Dickens, the usual high cost of the books preventing people in moderate circumstances from enjoying this luxury. But now, owing to the use of modern improved printing, folding and stitching machinery, the extremely low price of white paper, and the great competition in the book trade, we are enabled to offer to our subscribers and readers a set of Dickens' works at a price which all can afford to pay. Every home in the land may now be supplied with a set of the great author's works.

GLENN'S SULPHUR SOAP.

Glenn's Sulphur Soap is the **Original** and **Best** combination of its kind, and the one now generally in use. For sale by **All Druggists.**

BEWARE OF COUNTERFEITS.

Wholesale Depot,

C. N. CRITTENTON,
115 FULTON STREET,
NEW YORK.

Be progressive and keep abreast of the times. Avoid dyspepsia by using **Lard Compound** and **Cottolene,** a substitute for lard.

The highest medical authorities pronounce them healthful; and expert cooks commend them.

Our **Clairette** brand of cotton oil soap is the purest and best laundry soap in the market; as pleasant to the hands as genuine castile.

N. K. FAIRBANK & CO.,
CHICAGO AND ST. LOUIS.

OUR GREAT OFFER

TO SUBSCRIBERS

TO THE

AMERICAN ANALYST.

We will send the **ENTIRE SET OF DICKENS' WORKS,** *in* **TWELVE VOLUMES,** *as here described, all postage prepaid by ourselves, also* **THE AMERICAN ANALYST** *for* **ONE YEAR,** *upon receipt of* **$1.50,** *which is only* **50** *cents more than the regular subscription price of this paper.* Our readers, therefore, practically get a set of Dickens' works in twelve volumes for only **50** cents. This is the grandest premium ever offered. Up to this time a set of Dickens' works has usually been $10.00 or more. Tell all your friends that they can get a set of Dickens' works in twelve volumes, with a year's subscription to **THE AMERICAN ANALYST** for only **$1.50.** Subscribe now and get this great premium. If your subscription has not yet expired, it will make no difference, for it will be extended one year from date of expiration. We will also give a set of Dickens', as above, free and post-paid, to any one sending us a club of three yearly subscribers.

WHOM DO WE REACH?

We have often been asked the question, Is the ANALYST a chemical paper? Of course we have answered that it is not. A chemical paper, unfortunately, cannot be made self-supporting in these days. Then why do we call this journal the AMERICAN ANALYST? One answer is that it was so called in the beginning, and after a seven years' existence it would hardly do to change the name; but a further and better reply would be that, because the paper is called the AMERICAN ANALYST, it does not follow that it must be a chemical paper. The word analyst does not mean specifically one who makes a chemical analysis, but has a much broader meaning. The definition given by the best lexicographers is one who analyzes or who is versed in analysis, in any application of the word. The true definition of analysis is a dissolving, a resolution of a whole into its parts, solution of a problem, literally a loosing, resolving into its elements, undo, the resolution or separation of anything which is compound, as a conception, a sentence, a material substance or an event, into its constituent elements or into its causes. It is therefore clear that this paper is well named, though the name having been popularly applied exclusively to a chemist making chemical analyses, has led to a mistaken conception of the mission of this journal. As has been stated in a previous issue, we began our mission as an advocate of pure food and an opponent of sham products. In that field we have achieved great success, only one but marked evidence of which is found in the innumerable libel suits we have had to defend, and we say it with pride, successfully, having been in every instance sustained by the courts. We still continue our warfare against all shams and frauds, cooperating regularly with the various Boards of Health, national, State and municipal, to secure sanitary and food reforms through organized efforts, and it is conceded to be the only popular medium through which those bodies can bring their purposes and action intelligently before the general public. Reaching as it does all classes—manufacturers, merchants, physicians, chemists, and private families—all over the land, its influence is exerted over a vast radius, producing results as visibly marked as they are wide-spreading. The scope of this journal, however, is not limited to the missionary work above described. Its varied contents cover almost the entire field of scientific as well as social progress, and each yearly volume constitutes a compendium of current facts in nearly every department of knowledge such as can nowhere else be obtained in such comprehensive shape and so cheaply. We hope that we have made our position clear, and that hereafter we may not labor under the disadvantage of being judged by our title as a paper for chemists only, but that we shall be known as a paper for every intelligent reader.

MAGNETIC SUNLIGHT.

At the session, in Washington, D. C., on August 21st, of the American Association for the Advancement of Science, Professor Bigelow of Washington exhibited and explained before the mathematical and astronomical section a new scientific instrument called the aurora-inclinometre. Prof. Bigelow has been working for some years on the problem of the physical interactions between the earth and the sun, aside from those due to gravitation. Several important discoveries have already been made and a new field of investigation opened to science. It has been found that the same law which underlies the working of electricity and magnetism is operating on the sun, and gives the beautiful curves of the corona which are seen at the times of total eclipses. This corona is like the aurora, and is confined to a narrow belt in each hemisphere of the sun. Prof. Bigelow has recently discovered the causes of terrestrial magnetism and the variation of the magnetic needle all over the earth in periodic motions. It seems that the sunlight is also a magnetic field, and that the magnetized earth rotates in it, just like the armature of a dynamo. By a sort of magnetic refraction the rays of force enter the dark side of the earth in peculiar curves, pass through it in straight lines, and emerge in similar curves on the sunny side of the earth, turning all the needles in a corresponding way. Now the aurora marks the pathways by which these forces enter and leave the earth, or the modifications that are produced by them, or the ordinary magnetic field surrounding the earth, due to its permanent magnetism, and it therefore becomes essential to study carefully the data that they can give. Much study has been given to the aurora, but not along this line, for which also Prof. Bigelow has given the theory. Those three subjects, the corona, the aurora, and terrestrial magnetism, form one grand scheme and depend upon one law, the inverse of Newton's law of gravitation. To test the aurora a new instrument has been planned by Prof. Bigelow. It was constructed by the United States Coast end Geodetic Survey, and they have made it a model of beauty and efficiency. It will be sent to Alaska this autumn, where the aurora is seen in the best conditions.

UNIVERSAL STANDARDS.

The Geographical Congress recently in session at Berne, Switzerland, recommended the universal adoption of the metric system and also of the Greenwich meridian for the reckoning of time and longitude. The latter recommendation, however, is not likely to be universally adopted. Some time in 1884, it will be remembered, an international conference assembled at Washington with special reference to this same subject. The proposition, however, was not adopted as several of the delegates headed by those representing France rejected it, and their respective countries sustained them, so that the whole matter is left now where it was then. Besides, the persistent connection of this question with the metric system, which was apparent in the Berne Congress, taking the form there of a resolution that Great Britain ought to adopt that system, appears to be a fatal obstacle to establishing a universal first meridian. Great Britain with her enormous preponderance of maritime interests, supported by various other important maritime nations, could not give up the Greenwich prime, now used by a vast majority of the world's shipping. Since it is simply a matter of general convenience and utility for other nations to conform to this, it is strange to demand as the price of such conformity a complete revolution in the British system of measurements. Should that ever be effected, it would be on its intrinsic merits, and not for the purpose of procuring conformity to the English prime meridian, which is a matter that concerns the interests of other countries much more than those of Great Britain.

ARTIFICIAL PEARLS.

GEMS OF OCEAN MADE TO ORDER OF ANY SIZE.

A process for making real pearls by artifice is, according to Rene Bache, the basis of an application for a patent newly filed by an ingenious person who expects to find in his invention a source of wealth compared with which Monte Christo's means were poverty. The material of which pearls are composed is cheap enough. Take the shell of a pearl oyster and remove by grinding or with acid the rough outer coat. What have you left? A sheet of perhaps an eighth of an inch in thickness of pure pearl—the precise substance which the bivalve deposits around any foreign body, like a grain of sand or occasionally a little fish, that gets caught under its mantle, thus producing the pearls of commerce. Why not take this sheet of nacre dissolve it in acid, and then redeposit the pearl in layers about a buckshot suspended in the solution, thus imitating as nearly as possible the method of nature? If it were practicable to make pearls at all in this way, perfect ones could be formed every time, of any shape desired. There would be no difficulty in turning them out as big as billiard-balls. The trouble is that the concretions thus obtained would be mere lumps of carbonate of lime, lacking entirely the irridescence which in the pearl is due to structure. It is claimed, however, by this inventor that he has overcome the difficulty, so as to be able not only to manufacture pearls, but also to plate articles with the material, as forks and spoons are coated with silver. Conchologist Dall of the Smithsonian Institution, speaking about the practicability of pearl manufacture, exhibited a very remarkable treasure. It was a pearl as big as a pigeon's egg, of a most exquisite rose color, and the receptacle containing it was the fresh-water mussel wherein it had been originally formed. Explanation was made that the nucleus of this incomparable gem was nothing more nor less than an oval lump of beeswax, which had been placed a few years ago between the valves of the mollusk. To protect itself against irritation by this foreign body, the animal surrounded it with the pink nacre it secreted for lining its shell, thus transforming the bit of wax into an ornament fit for a royal crown. The mussel which produced this thing of beauty grew in an Ohio River and was kept in an aquarium while performing its unwilling task. It is a species of bivalve plentiful in streams all over the United States, and there is no reason whatever why anyone cannot make pearls in this way by keeping a few "unios," as they are called, in a tank at home. Care should be taken to introduce the intended nuclei well under the mantle of the fish, not making them too large, because an object the size of a pea will acquire a thickness of nacre much more rapidly than if there is a greater surface to be covered. The most beautiful mother-of-pearl, unless that of the abalone be excepted, is obtained from the nautilus, which is a cephalopod and related to the cuttlefish. Occupying only the mouth of its dwelling, the latter is composed of a series of empty chambers, each of which the animal has successively lived in and vacated as it grew bigger, building up behind it at each move a wall of purest pearl. These vacant rooms of pearl are all connected by a pneumatic tube, which enables the creature to so control the air supply in its house as to make the domicile lighter or heavier at will, in order to ascend or descend in the water. The shell is too thin to bear grinding, and so muriatic acid is used to remove the outer coat and disclose the exquisite nacre beneath. A method of treating such shells consists in drawing upon them with a brush and wax varnish any designs desired, after which they are placed in a bath of weak acid. The latter eats away the outer coat wherever it is not protected by the varnish, the result being a lovely cameo with raised figures in white on a pearly ground. Nature, however, beats Art hollow at this sort of work. In the cretaceous epoch, hundreds of thousands of years ago, there lived certain cephalopods, since extinct, which science calls "ammonites." The pearl they produced was a wonderful beauty, and many fossil ammonites dug up to-day have been so operated upon by the processes of decay as to form elaborate patterns on the shells in pearl and white. No artificial work can compare with the rainbow-hued richness of these relics of the past, reminders of that strange age when oysters and other mollusks had a more important place in creation than they now possess. Apparently, Nature does not make pearl for decorative purposes, else it would not always be on the inside of shells and hidden beneath an ugly coat of lime. The object for which it is intended is evidently to afford a smooth and comfortable dwelling for the soft animal within. The color of the nacreous deposit varies very much. Thus pearls themselves are white, black, blue, purple, pink, and even rarely green. Among the most valuable ones are the rose-tinted pearls produced by a species of couch found in the neighborhood of the West Indies. A single oyster may produce at the same time both white and purple pearls, according as the object enveloped in nacre is situated beneath a portion of the mantle which secretes the corresponding color. Concretions of peacock-hued material are sometimes found in the abalone, which fetch high prices as pearls. It is estimated that no less than $200,000 worth of abalone shells are shipped from the Pacific coast annually, the wholesale price being from $500 to $700 a ton. The finest pearls of the world come from the Persian Gulf, where the oyster beds produce $2,000,000 worth per annum. Because the divers are of rather light complexion, they blacken their bodies, so that they may not be seen so readily by the sharks. In the Sulu Sea women do the diving for pearls and prove very efficient in the work. It is their task to dive for crabs and other sea delicacies which the men folks like, and thus they have plenty of practice. It is here that the finest pearl shells are found, some of them measuring a yard across when opened. The pearl fisheries of Ceylon belong to England, the natives being employed to gather them on a basis of shares in the result. All sorts of superstition prevail among them, and a large business is done by sorcerers who sell charms to restrain the appetite of the sharks and to drive away the diabolical stingrays. Another peril which the diver dreads more than either stingray or shark is the giant clam that weighs nearly half a ton when full grown. It will snap off a man's leg like a pipe stem, if the victim chances to thrust a limb between its open jaws, or at all events will hold him until he drowns miserably. The average diver thinks it a fair day's work to secure one hundred pearl oysters in fifty feet of water. After being taken ashore, the mollusks are allowed to die when their shells open of their own accord. The pearls are classified by passing them through a series of sieves which assort them into different sizes. Those which are very small or defective are sold to make a preparation for sore eyes and nervous complaints that is very popular in the East. Gilded youth in India make it their fad to mix powdered pearls instead of lime with the betel nut they chew. In Saxony pearl mussels are carefully opened and examined upon being taken out of the water, without injuring them, special instruments being used for the purpose. Those which are found not to contain pearls are restored to their native element. It is only in the Gulf of California that regular diving gear is employed in connection with the pearl fishery. The beds there were pretty nearly destroyed one hundred and fifty years ago, when from three hundred to five hundred pounds of pearls were taken from them yearly. The latter were packed on mules and literally sold by the bushel. The most beautiful pearl in existence is "La Pellegrini," at present exhibited in a museum at Moscow. It is perfectly spherical, and so brilliant and pure as to appear almost transparent; weight ninety grains. The imperial crown of Austria contains a pearl of three hundred carats; but the biggest one in the world is the "Hope Pearl," now in London, which weighs three ounces and measures two inches in length, its estimated value being $60,000. There is a pearl in the Spanish regalia weighing four hundred carats; it was obtained from the Gulf of California. Green pearls come from the Marianne Archipelago. Two big ruby-red pearls were found at the Ceylon fishery ten years ago, and are owned by the rajah of the Sulu Islands. Pearls are very perishable. Great quantities of them have been found in old Indian mounds and tombs, showing that the savages did anciently appreciate their beauty, but they were so decayed as to be entirely worthless. Pearls should never be put into greasy or soapy water, nor should any fruit acid be permitted to come into contact with them. They can be kept best in magnesia. It was believed in early times that hollow pearls were caused by the oyster's taking fright at thunder when in the act of conceiving them. It is perhaps to be regretted that the story of Cleopatra's dissolving a great pearl in vinegar and drinking the mixture must be set down as mythical. It would take a very long time for vinegar to dissolve a big pearl, and any acid strong enough to dissolve it quickly could not be drank. Doubtless Egypt's fair queen had a great many huge pearls. One of them is said to have been sawn in two, the halves being used as pendants for the ears of the Capitoline Venus. What are known as "Roman pearls" are made by lining globules of glass with a substance derived from fish scales, which owe to it their irridescence.

RENE BACHE.

CHEAP SOAP.

A WORD OF CAUTION TO THE TRAVELING COMMUNITY.

"There are a good many thousands of professional traveling men in this country, and at least one in fifty of them has an affection of the skin of a more or less serious character," said a well-known dermatologist of this city. "The origin of these cases of skin disease may almost invariably be traced to hotel soap. Every person who has been a hotel guest, no matter where, is familiar with the much-worn and razor-edged cake of soap that lies in wait for him on the washstand in his room—sometimes in a not over-clean soap dish and frequently glued to the cover of the stand where the last occupant of the room, in his haste, permitted it to repose, the chambermaid not having disturbed it. Now you haven't the slightest idea in the world who the gentleman was who used that soap last, and singularly enough, few men, even the most fastidious, ever give the matter a thought. It would be an easy-going individual indeed, though, and one with phenomenal indifference to considerations of cleanliness, who would for a moment think of using a towel that showed signs of having done even the slightest service for the previous occupant of a hotel room; but instances are rare when the same guest will hesitate to use the soap he finds in the same room, although it may yet be damp and sticky from the part it took in the ablutions of the last person who used it. The traveling man does not stop to think that the hotel soap is unexcelled as a medium for the conveyance of cutaneous maladies from one person to another and frequently distributes diseases of the skin that are most difficult of eradication. The person who has occasion to stop at hotels, whether habitually or only occasionally, is not wise if he does not carry and use his own soap. If he is thoughtless enough to use the stock soap of the hotel rooms, wherever they may be, he deliberately courts the contracting of what may be a most distressing and offensive malady."

INDIAN ILLUMINATION.—Petroleum superseded vegetable oils for lighting purposes in India, and is being gradually driven out itself by the electric light, owing to the peculiar fitness of the latter for use in hot climates.

ACOUSTIC THERMOMETER.

TAKING THE TEMPERATURE BY TUNING-FORKS.

Perhaps some of our readers would hardly have suspected that there exists any connection between acoustics, or the science of sound, and the science of heat; but we would remind such that there is a general harmony amongst all the laws of the sciences, and as regards the phenomena which they govern, it must be remembered that they are all manifestations of the same "something," which we call energy. Sound and heat are surely not more widely different than are mechanical work and electric light, yet how easy it now is to obtain illumination by driving a dynamo. A suggestion recently made by Mr. S. Tolver Preston, of Hamburg, indicates very definitely one relation which sound may have to heat. He proposes to estimate temperature by means of tuning-forks! The idea, as expounded in the current issue of the *Philosophical Magazine*, is simple enough, and relates to the well-known fact that the note emitted by a resonance tube varies according to the temperature of the air which it incloses, and Mr. Preston's notion is to employ this in some way as a measure of temperature. One of the simplest aspects of the case may be thus illustrated: Suppose a tube, closed at the inner end, to be inserted somewhere in the wall of a furnace, or buried in some heated substance whose temperature it is desired to ascertain. Now, a tuning-fork of a certain vibrating period will, at normal temperature, vibrating in resonance with a tube possessing a certain length. It will be seen at once, therefore, that by changing the temperature of the tube, or of the substance in which the tube is buried, the tuning-fork will not respond. Another fork of a different vibrating period must now be selected in order to resound with the tube. It has been shown by the dynamical theory of Maxwell that since the pressure of a gas depends on the motion of its particles, the velocity of the propagation of sound depends on the normal velocity of the gas particles or molecules; in fact, that the sound-wave moves independently of the density and pressure of the gas. This applies, as will be at once apparent, to our proposed acoustic thermometer. For it is this normal motion of the molecules of the gas in the tube, the energy of which motion we call the "temperature," which is the sole factor in determining the velocity of sound, of which the tuning-fork employed with the tube is the mechanical indicator. The velocity of sound being as the velocity of the gaseous molecules, and the velocity of the molecules being as the square root of this energy, then, since the temperature is the energy, the velocity of sound in a gas is proportional to the square root of the temperature. If we have a tuning-fork whose vibrating period is mechanically adjustable, it is easy to perceive, then, from the above, that the temperature in the tube is inversely proportional to the square of the vibrating period of the fork. Or, if the length of the tube be adjustable—for instance, if the tube be telescopic—the temperature of the air in the tube, and, therefore, of the heated receptacle, or what not, in which the tube is placed, is evidently proportional to the square of the length of the adjustable tube. Now, zero Centigrade being 273 above the absolute zero, the Centigrade zero is then, of course, 273, expressed as absolute temperature. At 273 above zero Centigrade (which is 546 of absolute temperature), the molecules of the air have, of course, twice the energy they have at zero C. At 4×273 absolute temperature (819 above zero C.) the molecules of air will possess, in the same way, four times the energy possessed by them at zero C., and, therefore, twice the velocity which they had at zero C. (velocity being as the square root of energy). Sound would then be propagated in air in such a tube whose temperature is 819 deg. C. at twice the velocity of its transmission in air at 0 deg. C. So that a tube of air at 819 deg. C. would be in resonance with the same tuning fork as a tube of half the length resounds to at 0 deg. C. It is evident, therefore, that by varying the length of a telescopic tube, and employing a constant fork, we shall serve the same object as (conversely) varying the vibrating period of an adjustable fork and keeping the length of the tube constant. These are the theoretical considerations as given by Mr. Preston in the *Philosophical Magazine*. Some may see a way to propose some practical form of acoustic thermometer based on these principles, and to suggest some mechanical modifications which might make such an instrument extremely sensitive. We commend the notion to our organ-building subscribers.—*English Mechanic.*

GUTTA PERCHA.

ITS ORIGIN, MANUFACTURE, AND COMMERCIAL SIGNIFICANCE.

The price of gutta percha has nearly doubled in two years, and now rules at $1.30 per pound. This remarkable advance in the price of the article is attributed to two causes—the large quantities required in the manufacture of electric and other modern devices and the reckless destruction of the trees from which the gum is obtained. Gutta is the Malayan term for gum and percha is the name of the tree from which it is obtained; therefore the name may be translated gum of the percha tree. This gum or sap is not obtained by merely tapping the trees, as is done by the gatherers of crude rubber along the Amazon and its tributaries, but the Malays and natives of Borneo who collect gutta percha fell each tree from which gum is to be extracted, and thus the destruction of the trees and consequent scarcity of the product is explained. From 1854 to 1875, 90,000 piculs, weighing 133⅓ pounds each, of gutta percha, were exported from Sarawak alone, and this meant the death of 3,000,000 trees. As no trees are planted, the only thing which has saved this species of plant from annihilation is that it does not produce the gum in paying quantities until it is twenty-five to thirty years old. The method pursued in felling the trees is as follows: A staging is erected from fourteen to sixteen feet high, which enables the workman to cut the trees just above the buttresses or banees, as they are called. The tools used in felling are either "billiongs" or "parangs." A billiong is a kind of axe used by the Malays in felling, building and the like. The blade is of a chisel-like form, and the tang is secured at right angles to a handle by means of a lashing of rattan or cane. The parang looks more like a sword bayonet, and in the hands of a Malay is said to be a box of tools in itself, as with it he can cut up his food, fell a tree, build a house or defend himself. After the tree is cut down, some natives beat the bark with mallets to accelerate the flow of the sap, which usually runs slowly, changing color meanwhile. It concretes rapidly. The sap is boiled either with water, lime juice, or cocoanut oil, and it is generally run into moulds which sometimes produces forms of the hardened material resembling various animals in shape. The gutta percha tree, the vernacular name of which is taban, also bears a fruit about an inch long, ovoid in shape, which is eaten by the natives. In Siak, Sumatra, a vegetable butter is prepared from the seeds of this fruit. The trees attain to a height of from 60 to 80 feet, with a diameter of from 2 to 4 feet. The wood is soft, fibrous, spongy, of a pale color, marked with black lines, these being the reservoirs of the gutta percha. The yield of a well grown tree of the best variety is from 2 to 3 pounds of gutta percha, such a tree being about 30 years old, 30 to 40 feet high, and 1½ to 3 feet in circumference. Gutta percha is used in a multitude of different ways. It has been found to be the best non-conductor of electricity and most perfect insulator that has yet been discovered. A wholesale dealer in the article recently stated that scarcely a week passes but some one calls upon him claiming to have found a substitute for gutta percha, but none of the substitutes so far offered has been able to meet the requirements. No other substance has been found so efficient for submarine cables, and according to a statement recently published in the New York *Sun*, the Atlantic cable laid in 1857 is still preserved by its gutta percha covering. This article retains its form at a temperature below 115° F. It is insoluble in water, even in salt water, and it is also insoluble in alkaline solutions and various acids, and is, therefore, made into vessels to contain these substances. By mixing bisulphate of carbon with gutta percha a liquid cement is produced, which is employed in putting patches upon shoes, thus dispensing with sewing, and securing a neater appearance on the shoe. The same cement is also used in repairing rabbit skins. These skins are weak and are easily torn; but by backing them with this cement they are made tougher, and are sold in some cases by unscrupulous dealers as squirrel skins. Another use to which gutta percha has been put is placing it around the bottoms of pantaloons to protect them from wear. It has been made so thin that a yard of it weighed only 7 to 8 pounds. A piece of this was placed around the bottom of the garment, then an inch of cloth was turned in on top of the gutta percha, a hot iron was passed over it, which rendered it secure, thus saving the expense of sewing to the manufacturer. Since gutta percha has advanced so greatly in price, it has been found impracticable to use it for this and many other purposes, in fact it has been stated that a large engineering firm in the United States proposed to enter upon the manufacture of submarine cables on an extensive scale, but were unable to carry out their purpose, on account of the scarcity and the difficulty of obtaining gutta percha. Efforts have been made to check the destruction of this most useful tree by substituting tapping for felling, but the greed of the natives is so great that they adhere to the latter method, because it gives them more of the sap for immediate marketing, being regardless of the fact that the trees are being exterminated. The only remedy for the great scarcity of the article seems to be the cultivation of the tree, and measures of this kind will have to be adopted if gutta percha, which seems to be an article entirely indispensable in some lines of manufacture, retains its place in the commerce of the world. —*Scientific American.*

CATTLE DISEASE.—An important discovery has apparently been made by M. Mandereau, of Besancon, which, if, corroborated, will permit of the easy recognition tubercle in cattle. M. Mandereau found tubercle bacilli in the aqueous humor of the eye in more than a score of bovines suffering from various stages of the disease, even in the very early stages, it appears.

AN ERUDITE MENU.—In looking through our collection of remarkable menus we recently came across the wonderful compilation set before the savants of the Oriental Congress at Stockholm. It forms a small volume of eighteen pages, elegantly bound, and comprising the contributions of distinguished scholars, each of whom discourses of one of the dishes in the menu in one or other of sixteen Oriental languages. The introductory "sup" or nip of schnapps, without which no dinner in Scandinavia is complete, is also honored with an original song in the Kairs tongue. Potage a la suedoise receives a compliment in Getziani from M. Dillman, besides a song in Chinese from Gustav Schlegel; and Prof. Max Muller sings in Sanscrit the praises of Saumon a l'imperiale. Filet de bœuf is distinguished by a verse in Malay by M. Klinkert, and ptarmigan by another in Javanese by A. C. Vreede. Mr. Sayce, in like manner, does homage to the salad in some recondite tongue, probably Chaldaic or Assyrian. E. Amelineau treats of Artichaut au beurre in Coptic; J. Leiblin, of Gateau a la Victoria in hieroglyphics; D. H. Miller, of the ices in Himyaritic; H. Almquist, of the cheeses in an epigram in Bichare; Bu-sa-ta Mansitu, of the Dessert International in Japanese, and so forth. The menu concludes, according to the Swedish custom, with "Thanks for Dinner," written in Persian by the Oriental scholar, Habit.

LUNAR LORE.

DISCOVERIES ATTAINED THROUGH ASTRONOMICAL PHOTOGRAPHY.

Astronomical photography has accomplished many wonderful results, but nothing perhaps more surprising than its discoveries upon the moon. The moon is so near by, and has been so carefully studied with the most powerful telecopes for hundreds of years, that the astronomers had come to think that they knew pretty much all about it, or at least about that face of the moon which is turned toward the earth. But it turns out that photography possesses the power to reveal things upon the moon which cannot be seen by the eye, even with the aid of the best of telescopes. A careful study of the negatives of the moon made with the aid of the great Lick telescope has revealed the existence of many unknown objects there, including great crater mountains and rifts or chasms in the surface of the moon, as well as some of those mysterious objects that go under the descriptive name of bright streaks or rays. Near the great crater which we will call Corpernicus, another crater of nearly equal dimensions is shown upon the negatives although it is absent from the most elaborate maps of the moon and cannot be seen even with the Lick telescope, except when the magic eye of the camera, instead of the human retina, is applied to look for it. When it is considered that this mysterious crater represents the remains of a mountain ring more than fifty miles in diameter, it appears exceeding strange that it should escape detection by the telescope when directed to the moon, and yet be visible upon a photograph of the moon. The reason appears to be that the walls of this newly discovered crater were long ago destroyed, being raised by some denuding force nearly to the level of the surrounding surface. It is consequently, but the remnant of a great crater ring. Even in that condition, however, it would be visible to the eye, but for the fact that its huge neighbor, Copernicus, whose walls are still standing to a great height, is surrounded by enormous masses of luminous material, which looks like lava that must have overflowed the surrounding country ages ago, and reflects back the light of the sun to our eyes with overpowering brilliancy The glare of this broad reflecting surface, covering hundreds of square miles, is so great as to conceal the comparitively low relief of the broken crater ring. In fact, it is not improbable that Copernicus is responsible for the disappearance of the other great crater which doubtless was the predecessor of Copernicus, and once towered up to an equal height above the surrounding plains. After it had ceased to be an active volcano, and Copernicus had burst forth, the latter probably overwhelmed it with torrents of lava, which, filling up the space within its broken walls nearly to the level of their tops, submerged it, so to speak, beneath the new surface thus formed, so that only the summit of its broken walls remains to be caught by the acute vision of the photographic plate. In other parts of the moon similar events appear to have taken place, and there are a number of large craters, enormously greater than any volcanic craters upon the earth, which seem to have been buried by the outburst of lava from subsequently formed volcanoes in their neighborhood, so that only portions of their mountain walls now remain visible. Another discovery, also arising from inspection of the negatives made with the Lick telescope, relates to the wonderful system of bright rays surrounding the most perfect crater in the moon, Tycho. This extinct volcano is some fifty-four miles in diameter, and is surrounded on the outer side of its lofty walls by a comparatively level region, some twenty-five miles broad, of a much darker hue than that of the crater itself or of the surrounding country beyond. The hundreds of great streaks which radiate from Tycho like the spokes of a wheel, varying in width from ten to twenty or thirty miles, and in length from a few miles to nearly 2,000 miles, have always appeared, when viewed with a telescope alone, to take their rise from the outer edge of the dark rim surrounding the crater, but the Lick negatives show that some of the streaks at least pass through this dark rim and extend clear up to the very walls of the crater. The suggestion that these mysterious streaks had their origin in the volcanic energy of Tycho when it was still an active crater, is strengthened by this evidence that the streaks actually reach to the crater itself. These discoveries are likely to give renewed interest to the study of the moon's surface, and while it is perhaps too much to expect that a great deal of light will be thrown by astronomical photography upon the question whether evidences of the present or former existence of life upon the moon can be detected from the earth, yet there can be no question that a new method of attacking the many problems that still remain to be solved concerning the character and condition of our satellite has been placed within the reach of astronomers.

ON THE SCENT.

AN INVESTIGATION OF DOG'S SENSE OF SMELL.

Dr. McPherson gives the following very interesting description of experiments made to determine whether the scent of a dog after his master was due to the boots he wore. To solve this interesting problem, Dr. Romanes took a most intelligent setter, which he had for eight years made his companion upon his shooting excursions. The animal's devotion to him he had often tested most minutely, and his sense of smell was known to be exceptionally acute. He walked over the park lands round his house unseen by the dog for about a mile, having on his ordinary shooting boots, and slipped over a wall to watch operations. As soon as the dog was let off, he broke away at full speed on the trail and reached him in his hiding place in a few minutes. He was repeatedly put on a stranger's track, but he would not follow him. Next he was taken into the gunroom, where he saw his master making ready to start for shooting. He then left his room and went to another part of the house, but his gamekeeper left the house by the back door, walked a certain distance and concealed himself. The dog, now nervously anxious to follow his master, was led to the keeper's tracks by a servant. He followed his trail for a few yards, but he found that his master was not with the keeper. Accordingly, after hunting about in all directions with nervous excitement, he returned to the house. Dr. Romanes then collected eleven men about the place, and directed them to walk close behind one another in single file, each man taking care to place his feet in the prints of his predecessor. In this procession Dr. Romanes took the lead, while the gamekeeper brought up the rear. After walking 200 yards, he turned to the right, followed by five of the men; the remainder turning at an angle to the left, all walking as before in single file for a considerable distance. All then hid themselves. The dog which saw nothing of these proceedings, was then put upon the common track of the whole party. He followed it with avidity till he came to the point of separation. For an instant only he seemed to hesitate, but chose his master's footsteps to the right. Upon another day Dr. Romanes gave his shooting boots to a stranger, who walked with them over the park for a considerable distance. When the dog was led to this trail he followed the scent with the eagerness usually seen when tracking his master. This was a remarkable discovery. Next he put on the stranger's boots and walked over the park in another direction. On being taken to the trail he would not be coaxed to follow it at all. This was even more remarkable. The stranger walked over the park barefooted, but the dog would not follow that trail. Dr. Romanes then walked over the park with bare feet and he followed this trail, but not nearly so eagerly as when he had on his shooting boots. He seemed to be always in doubt as to the correctness of the track and seemed terribly put about. The results of these experiments stimulated him to go on further with his investigations, in order to find out the secret of the discriminating faculty. He walked over the park in new shooting boots, but he would not follow the trail—the boots were strange. Nezt he glued a layer of stiff brown paper to the soles of his old shooting boots, and walked over the park with them, and the setter when led along the trail, paid no heed to it, till he came to the place where, owing to the brown paper being worn through at the heel, the boot had touched the ground. Here he immediately recognized his trail and speedily followed it up. Again he walked 50 yards in his old shooting boots (without the brown paper), then 100 yards in his stockings, and then 100 yards barefoot. The dog followed the first part of the trail at full speed, and continued to run at the same rate till the end. Changing the experiments, he soaked his ordinary shooting boots in the oil of aniseed, and walked with these over the park. But this strong odor did not interfere with the dog's scent, for he ran him down as quickly as before. That is a most curious fact. Dr. Romanes came to the conclusion that this setter distinguished his trail from that of all other men by the peculiar odor of his boots, and not by the particular smell of his feet. The exudations from his feet required to be combined with those from the boot leather, and brown paper can stop the transmission of the scent of both. He also afterwards concluded that the whole body of man exhales a peculiar odor which a dog can recognize as that of its master amid a crowd of other persons.

IMITATION GOLD.—A well-known English scientific gentleman has been experimenting on a metal resembling gold for nearly a year, and has now got it down to almost perfection. He stumbled on it first accidentally while analyzing some metals, and when he realized what he had found he went to work and soon produced a metal which puzzles the best jewe'ers, is as heavy as gold, and to all appearances is of the precious metal itself. When the gold test is applied to it the acid boils up a little, but gives no other evidence that the metal is other than gold, and when wiped off no mark or spot is left, as is the case when the test is applied to brass. It can be manufactured at a comparatively small cost. Aluminum composite is said to be chief factor, 5 to 8 per cent.

THE PIG IN CHINA.—Chinese life is a perpetual surprise. Man's most faithful four-footed friend, the dog, is relegated to the outcast world and his place filled with the more edible pig. Under these auspices, the dog reverts to the ancestral wolf, and is hardly distinguishable from that disagreeable brute, while the hog becomes a distinguished member of society. Every Chinese porker has a name and answers it, especially when called to meals, as promptly and knowingly as a well-trained watch-dog. He lives with the family, and sleeps either on the foot of his owner's bed or else in the baby's crib. After breakfasting *en familie*, he sets off on a constitutional walk through the city and suburbs. He makes calls upon other pigs of equal social standing, invades and robs every garden whose gate may be open, and usually refreshes himself by a walk in the surf on the beach, where he whets his appetites with a dozen oysters on the whole shell and a few defunct fishes.

AN AWKWARD MOMENT.—One of the most embarrassing accidents that ever happened to an actress befell Mrs. Potter while she was playing "Cleopatra" in this city, says the Cincinnati *Commercial Gazette*. She had reached the asp juncture in the play, and the slave had brought that instrument of suicide. Her "Cleopatra" costume was a revelation in more than the millinery sense of the word, but no one suspected it was not securly moored. She grasped the asp with one hand and made arrangements for its application with the other, when something suddenly slipped. Whether a string broke or a pin forgot its duty nobody knows. Bald-headed veterans, who had for decades been familiar with the glories of the ballet and amazon march, turned red and looked uncomfortable, and an infant in the gallery set up a hungry wail. Mrs. Potter did not lose her presence of mind, however; she readjusted herself with neatness and alacrity, the asp was tendered his nourishment, and the play proceeded.

ARSENIC.

A PROTEST AGAINST ITS USE IN THE ARTS AND MANUFACTURES.

The fight already vigorously and pluckily begun against the unrestrained employment of arsenic in the manufactures and the arts promises to be a long and a hard one. On one side will be scientific protest, backed by demonstratable fact and by common sense. On the other, will be the manufacturer, who sees a profitable branch of trade seriously imperiled, and who is prepared to come to its rescue with arguments of the golden and substantial sort which so appeal to the professional lobbyist. Public sentiment, at least in the beginning, will not be a weighty factor in the matter; for public opinion is, on the subject, unformed, indifferent and sluggish. This latter fact points out to our workers the line in which their efforts may most profitably be directed. Public sentiment must be aroused to the dangers of the uncontrolled use of arsenic. Warnings and facts must be given, and re-stated, and given again, with the unwearied persistency which is the price of arresting public attention; given in talk of friend with friend, in serious counsel of the physician to his patients; above all, through the daily press, whose columns are open to endless discussion of a matter so important to the general public, and whose editorial bias, up to date at least, seems distinctly on the side of the reform. It is quite time the reform came to be; and there is good cause to hope that enlightened public opinion will soon insist on its coming to be, when once the facts of the case have been so far realized that public opinion is aroused and formed. First, the fact, monstrous in every sense of the word, that there are imported into the United States, yearly, upwards of nine millions of pounds of arsenic; and that this vast bulk of shockingly dangerous material is so far made use of, before the twelvemonth is passed as, next year to necessitate importation of an equal amount. How is it utilized? Considering how infinitesimal, comparatively, is the amount likely to be employed medically and pharmaceutically, what an immense remainder is to be accounted for to the defenders of the public health. There is little doubt, when we take into account the surprising variety of articles which have been known to communicate arsenical poisoning, that there is scarcely a manufacturer of personal furnishings or household plenishings at whose door may not be laid the charge of ignorance or deliberately imperilling the health of his fellow-beings, by sending out, under his labels, goods capable of communicating poison. Now we have a patient poisoned by the wearing of a cheap, dyed glove; now by a pair of bright bonnet strings; now by sleeping in a room "æsthetically" papered; now by inhaling the impalpable dust from arsenic-tinted curtains blowing in the wind; now a baby sucks arsenic from the corner of its pretty bed quilt; now a child suffers from eating candies wrapped in arsenic-loaded papers. It all reads like some sensational tale in a penny-dreadful newspaper; but it is nevertheless all a deplorable and shameful fact, and will so continue until our laws demand that a label stating the presence of poison be affixed by every manufacturer to every article sent out by him containing arsenic, as must now be done by every druggist with the prescriptions which contain so farcically smaller a relative amount. Naturally manufacturers object to this, and already protests, droll in their bitter animus, their lack of logic and manifest self-contradictions, are met with here and there. Thus we are told by the maker of wall paper that the maker of textile fabrics is all to blame, and the maker of textile fabrics solemnly assures us that he could not afford to use anything so expensive in his business as arsenic, which, we discover on inquiry, costs the prohibitory sum of two cents a pound! The case is, however, so obviously a bad one for the manufacturer that his fight will probably be conducted in "still hunt" fashion, with the weighty yellow arguments hinted at above. Against such argument public opinion, vociferant, not to he placated, is, as we have said, the only effective weapon. Let each of us do his share toward creating such opinion. Facts and facts and facts must be the battering rams with which we break our way through ignorance and indifference. Useful facts to possess ourselves of would be the names of the principal manufacturing houses which are large importers and purchasers of arsenic. The mere publication of their names, and the approximate amount of arsenic purchased by each yearly, might have a salutary effect in so turning the inquiring public eye in their direction as to make it awkward for them to keep silence. Naturally, the most useful facts of all are those relating to accidental poisonings by arsenic in some manufactured articles; facts which to have their full weight should include the demonstration of the arsenic, not only in the suspected article, but in the urine of the patient, a point of immense importance not only in diagnosis, but as legal evidence..—*N. E. Med. Gazette.*

SCHIZOMYCETES.

THE SMALLEST FRIENDS AND FOES OF MAN.

Dr. Koch's successful struggle with the tubercle bacillus, discovered by him eight years ago, has drawn the attention of the whole educated world to the various species of those minute simple organisms, which consist of one, or at most of only a few cells, and propagate by fission, *i. e.*, the parent cell, which is barely $\frac{1}{500}$ millimeter in diameter, divides into two daughter-cells, each of which grows and subdivides in the same manner, whence the name *Schizomycetes.* These organisms being without chlorophyll—the green coloring matter essential to the proper independent development of all plants—become parasitic on dead or living organisms, and, preying and propagating on organic substances, in still or running waters, are taken into the digestive organs of man and beast, and thence find their way into the system. Some make their abode in the passages of animals, and being reduced to dry dust are inhaled by us. The motes which we see in the sunbeam's track are on an average a thousand times as heavy as these minute organisms in their dry state. The Schizomycetes carry out the same destructive operations in the human or animal systems, as they do in plants and in so doing, generate the most fatal diseases. The general form of Schizomycetes guides to their division into four leading types: (1) Spherical-shaped, or *cocci*, which, according to size, are again subdivided into *micrococci* and *macrococci*; (2) rod-shaped, the shorter known as *bacteria*, the longer as *bacilli*; (3) thread-shaped, and (4) spiral-shaped. In the course of their development Schizomycetes vary in shape with varying conditions of sustenance, so that probably some of them which are known under one or more forms, may sometimes assume other forms under which they are not recognized. Schizomycetes are for the most provided with tentacles, which aid them in their movements to procure food. Apart from the ordinary method of propagation by fission into two equal organisms, Schizomycetes, like ordinary fungi, also throw off spores, that is to say, parts of themselves, which germinate and produce fresh fungi. Subject to extreme cold or heat they remain dormant, but awaken with full vigor on being subjected to favorable conditions. Schizomycetes are known to have lain dormant for thousands of years in dry air without losing their vitality. Death occurs only on complete exhaustion of the means of subsistence; but although it is consequently very difficult for us to destroy them, they are frequently eradicated by other microscopic organisms. The struggle for existence is waged as fiercely in their ranks as among higher organisms. The appearance of a new species may be the signal for the disappearance of the hitherto dominant race. Schizomycetes, finding their subsistence in foreign bodies, set up a process of decomposition in those bodies, and to their agency is due the conversion of manure and refuse into plantfood; meats that taste "high;" all food-substances that begin to "smell," are infested by them. When vegetables, or milk, or substances containing sugar turn sour, it is due to chemical changes set up by them. Fermentation is due to their activity and so is the phosphorescence on decomposing meat or fish. But in these processes of decomposition the Schizomycetes for the most part work out their own destruction. They generate substances (*ptomaines*) which arrest their powers of decomposition and reproduction, and finally poison them. This fact forms the basis both of Pasteur's and of Koch's treatment. These creatures subsist as well on animal as on vegetable substance, and in fact find the most favorable conditions in the human body. Here a single germ taken in with the food or with a breath may generate a hundred, thousand in the course of seven or eight hours. They first fasten on the mucus membrane where, breeding rapidly, the work of destruction is soon in full swing. As soon as they have penetrated through the mucus membrane, they get taken up by the small blood vessels and circulate through the whole system. One of the first discovered of the vegetable parasites was the *anthrax* fungus, found in the spleen and other internal organs of herbiverous animals, hares, rabbits, mice, birds of prey, geese, fowls, ducks, sparrows, etc. The slaughter of animals thus infected, the mere handling of their flesh, skin, or hair may result in the communication to man of the poison. Still more fatal are the species to which the several contagious diseases are attributable; and the Schizomycetes of the eye are scarcely less to be dreaded. Finally as possessing historic interest we may mention the fungus which exists in the mouth of man and other mammalia, and causes the decay of the teeth. The self-same fungus has been found in the tartar on the teeth of Egyptian mummies. In fact there is evidence of the existence of Schizomycetes in the carboniferous era, long before the appearance of man on earth. Science has now entered on a crusade against these minute but formidable foes of humanity, but to enable it to reach its desired goal, we must redouble our energies to prevent the spread of the fungi, by all due sanitary precautions.—*Ueber Land und Meer.*

DAMMING THE NILE.—It is now the intention of European engineers to store the waters of the Nile to such an extent as to enable a greater extension of the cotton and sugar cane crops in that region.

VALUABLE PLATE.—Many years must necessarily elapse before the collections of gold and silver plate in this country attain the gigantic proportions of those owned by the royal and imperial families of Europe. Thus the gold and silver plate of the house of Orange at The Hague represents a value of $6,500,000, and includes the trifle of two thousand silver dinner plates. That of the British Sovereign amounts to $10,000,000, that being the estimated value of the plate used during the recent state visit of the German Emperor. The collections of the Austrian and Russian Courts are even larger, while the Duke of Cumberland, eldest son of the last King of Hanover, heads the list with no less than nine tons of gold and silver plate.

A FEW DEFINITIONS.—The poet Tennyson can take a worthless sheet of paper and, by writing a poem on it, make it worth sixty-five thousand dollars. That's genius. Vanderbilt can write a few words on a sheet of paper and make it worth five million dollars. That's capital. The United States can take an ounce and a quarter of gold and stamp upon it an "eagle bird" and make it worth twenty dollars. That's money. The mechanic can take material worth five dollars and make it into a watch worth one hundred dollars. That's skill. The merchant can take an article worth seventy-five cents and sell it for a dollar. That's business. The ditch-digger works ten hours a day and shovels three or four tons of earth for two dollars. That's labor.

BRIGHT STORIES.

THE CHAIR-MENDER.

From the French of Guy de Maupassant.

It was at the end of the opening dinner of the hunting season, at the house of the Marquis of Bertrans. Eleven hunters, eight ladies and the country doctor were seated at the brilliantly lighted table, which was covered with fruit and flowers.

They had just been talking of love, and a warm discussion had arisen, the old question as to whether one could love truly once or more than once. Many cases were brought up of people who had had but one serious love, and of others who had repeatedly loved fervently. Most of the men contended that passion, like disease, could attack the same person many times, and so severely as to kill him, if any insurmountable obstacle arose.

Although this position was unassailable, the ladies, whose opinion was based more upon poetry than on observation, maintained that love, true love, could come only once to mortals, that it was like a stroke of lightning, and that the heart once touched by it was thenceforth so empty, ravaged and seared, that no other strong feeling, no dream even, could spring up in it.

The marquis, who had loved often, opposed this idea very strongly.

"I know," said he, "that a man can love many times with all his heart and soul. You tell me about people who have killed themselves for love, as proofs of the impossibility of a second passion. But I tell you that if they had not been so stupid as to kill themselves, and thus lose all chance of change, they would have been cured, and would have done the same thing over and over again until they died a natural death. Lovers and drunkards are much alike—whoever has drunk, will drink again, and whoever has loved, will love again. It is merely a matter of temperament."

An appeal was made to the doctor, an old Parisian, who had retired to the country, and all begged for his opinion. But he had none.

"It is just as the marquis says," he said; "it is a matter of temperament. For my part I know of one passion which lasted for fifty-five years, without a day's intermission, and which was ended only by death."

The Marchioness clapped her hands, exclaiming, "How beautiful! And what a dream to be loved like that! What joy to live for fifty-five years surrounded by such a deep, strong affection. How happy he must have been, and how blissful his life, who was so beloved."

The doctor smiled and said: "You are quite right, madame, in thinking that the beloved one was a man. You know him; he is M. Chouquet, the village druggist. As for the woman, you knew her, too. She was the old chair-mender who used to come to the chateau every year. But I will tell you the story."

The enthusiasm of the women had cooled and their disappointed faces said plainly, "Pooh!" as if such love could come to none but elegant distinguished beings, who alone were worthy of the interest of refined and properly conducted people.

"Three months ago," continued the doctor, "I was called to the death bed of this old woman. Accompanied by her two big black dogs, her friends and guardians, she had come to the town the night before in the wagon which served her for a house, drawn by the old mare you have seen. The cure was already with her when I arrived. She named us executors of her will, and in order that we might understand her last wishes, she told us the story of her life, the saddest and strangest story I ever heard.

"Her parents were both chair-menders, and she had never lived in a house built on solid earth. As a little thing she wandered about ragged and dirty. The family always stopped by the roadside, at the entrance of the villages, and unharnessed the horse, who browsed about, while the dog slept with his nose on his paws. There the little girl played in the grass, and the father and mother, in the shade of the wayside oaks, patched up all the old chair seats of the neighborhood.

"They talked but little in that wandering home. After a short discussion as to which had better go the rounds of the houses, with the same old cry of 'Chairs to mend!' they would sit down and weave their straw in silence. When the child wandered too far away from the wagon, or tried to make friends with some village youngster, she was recalled by her father's angry voice: "Come back here, you good-for-nothing!" Such were the only endearments which she knew.

"When she grew older she was sent to collect the wornout chairs. In this way she made some acquaintances among the children, but it was now the parents of her new friends who called roughly to their children, 'Come back here, you good-for-nothing! Don't let me see you talking with bare-footed children!' And often the small boys threw stones at her.

"Some ladies had given her a few sous, which she kept with great care. One day—she was then eleven years old—as she was going about in this neighborhood, she met little Chouquet behind the cemetery. He was crying bitterly because another boy had stolen two centimes from him. The tears of the little fellow, one of the children whom in her simple neglected mind she had always thought happy and contented, moved her deeply. She went up to him, and when she learned the cause of his grief, poured all her savings—seven sous—into his hands, he taking them as a matter of course and speedily drying his tears. Then, wild with delight, she was emboldened to kiss him. As he was busy examining his money he let her do it. Finding that he did not repulse her she kissed him again, gave him a warm hug and then ran away.

"What did she think about in her poor little head? Did she love this youngster because she had sacrificed her modest fortune to him, or because she had given her first kiss of affection? The mystery is the same for both great and small.

"For months she thought of nothing but the corner of the cemetery and this urchin. In the hope of seeing him again she stole from her parents a sou here, another there, from the price of a mended chair or from the money given her to buy food. The next time she came to the town she had two francs in her pocket, but she could not contrive to do more than see the little apothecary, spotlessly clean, standing behind the windows of his father's shop between a crimson flask and a jar of leeches. She only loved him more than ever, fascinated and over-awed by the splendor of the colored water and the transfiguration of the shining crystals.

"She treasured his memory secretly, and when she met him the next year playing marbles near the school with the other boys, she rushed up to him, threw her arms around him, and kissed him so violently that he began to howl with fear. Then she gave him her money to pacify him. There were three francs and twenty centimes, quite a fortune, and he stared at it with big eyes, took it, and let her caress him as much as she wanted to.

"For the next four years she gave him all the money she could get, and he pocketed it deliberately in exchange for the kisses which she was allowed to take. Sometimes it would be thirty sous, sometimes two francs, once it was only twelve sous, which made her weep with grief and shame, but it had been a hard year; and the last time it was a great round five-franc piece, which made him laugh with joy. She thought of nothing but him, and he waited impatiently for her return, and delighted her heart by running to meet her when she came.

"Then he disappeared. He had been sent away to school. She found out that easily enough by asking questions. So she used all her wits to try and change the route which her parents took, in order to make them pass through the village during the vacation. She succeeded at last, but it was now two years since she had seen him, and she scarcely knew him he had changed so much. He had grown larger and better looking, was very imposing in his gold-buttoned coat, and passed proudly by pretending not to see her.

"She wept over it for two days, and from that time she suffered unceasingly. She came back again every year and saw him without daring to greet him, while he did not even condescend to look at her. She still loved him hopelessly. 'He is the only man in the world that I ever saw, doctor. I do not even know whether there are any others,' she said to me.

"Her parents died in the course of time and she worked on in their trade, but she now had two dogs instead of one—two terrible dogs, with whom no one would dare to meddle.

"One day, on her return to the village in which lived her heart's idol, she saw a young woman coming out of Chouquet's shop, leaning on his arm. He was married and that was his wife.

"That night she threw herself into the pond in the square by the mayor's house. A belated drunkard fished her out and carried her to the druggist's shop. Young Chouquet came down to take care of her, worked over her apparently without recognizing her, then said roughly: 'How foolish you are! How could you do such a thing?'

"He had spoken to her! That was enough to relieve her, and she was happy for some time after.

"He would not take any pay for his trouble, although she tried to insist on his doing so.

"And so passed her whole life. She mended her chairs and dreamt of Chouquet, and every year she saw him through his shop windows. She fell into the habit of buying small supplies of medicine from him, so that she still saw and spoke to him and gave him money.

"She died last spring, as I just said. After having told me her sad story, she begged me to give the savings of her life to him whom she had loved so patiently, for she had worked only for him, even starving herself at times in order to increase her hoard and to be sure that he would think at least once more of her when she was dead.

"She gave me 2,327 francs, twenty-seven of which I left with the curé to pay the funeral expenses, and the rest I took away when she finally ceased to breathe.

"The next day I went to see the Chouquets. They had just finished breakfast and were seated opposite each each other, with a satisfied, important look on their stolid, ruddy faces. A strong smell of the apothecary's shop pervaded the place.

"They asked me to sit down, and offered me a glass of kirsch-wasser, which I accepted. I then began my story in a trembling voice, feeling sure that it would make them weep.

"Just as soon as he understood that he had been beloved by this wanderer, this chair-mender, Chouquet was filled with indignation, as if she had stolen from him his honor and reputation, the esteem of men, and all that he most valued.

"His wife, who was equally angry, repeated again and again, 'The impudent creature! the impudent creature!' as if she could think of nothing else to say.

"Chouquet rose in his wrath and strode up and down the room, his Greek cap tilted over one ear, stammering, 'Did you ever hear anything like that, doctor! What a thing to happen to a man! If I had only known it I would have had her arrested and put in prison, and she would have found it hard to get out, I promise you."

"I was completely surprised at the result of my charitable errand, and was at a loss what to do or say; but as I had still my commission to finish, I continued.

"She instructed me to give you her savings, which

amount is 2,300 francs; but as what I have just told you seems so very disagreeable, perhaps it would be better to give the money to the poor.

"They both stared at me, dumb with amazement. I took the money from my pocket—a miserable collection of all sorts and kinds, gold and copper mingled—and asked, 'What will you have done with it?'

"Mme. Chouquet was the first to recover herself. 'Well, I suppose, as it was this poor woman's last wish, I think we can hardly refuse.'

"'We can always buy something for the children with it,' murmured her husband.

"'Just as you please,' I said drily.

"'As long as she wished it, you might as well give it to us,' they added. 'We can find plenty of good uses for it.'

"I gave them the money, bowed, and took leave of them.

"The next day Chouquet came to see me and said rudely, 'That woman left her cart here, didn't she? What have you done with it?'

"'Nothing. You may take it if you want it.'

"'Very well. It will do for a shed in my kitchen garden,' and he went out. I called him back and said:

"'She left an old horse and two dogs besides. Don't you want them?'

"He stopped in surprise. 'No, indeed; what could I do with them? You may dispose of them as you please.'

"And he laughed and held out his hand to me. I took it, for how could I do otherwise? It would not do for the doctor and druggist in a little village to be enemies.

"I kept the dogs, and the curé, who has plenty of room, took the horse. The wagon serves Chouquet for a shed, and he bought five railroad shares with the money."

"That is the only case of deep love I have ever known."

The doctor was silent. The Marchioness, with tears in her eyes, said with a sigh, "Only women know how to love."

DOMESTIC DIETETICS.

SPECIALLY PREPARED, FROM PRACTICAL TESTS, FOR THE LADY READERS OF THE "AMERICAN ANALYST."

SEASONABLE FOOD.

September.

GAME AND POULTRY.—Pigeon, chicken, duck, woodcock.

MEATS.—Beef, mutton, lamb, veal, ham, kidneys, liver, venison.

FRUITS.—Apples, bananas, blackberries, gooseberries, huckleberries, grapes, melons, oranges, peaches, pears, pineapple, plums, raspberries, currants.

FISH.—Bass, blackfish, bluefish, clams, cod, crabs, eels, flounders, halibut, herrings, lobster, mackerel, mussels, porgie, prawn, rockfish, salmon, trout, sea bass, sturgeon, turtle, white fish, whiting.

VEGETABLES.—Beets, beans, cabbage, carrots, cauliflower, corn, cucumbers, egg-plant, garlic, lettuce, onions, parsley, parsnips, potatoes, radishes, rhubarb, savoy, shallots, spinach, squash, tomatoes, turnips.

PRACTICAL RECIPES.

VEGETABLE SOUP.—Wash half a pint of pearl barley and let it soak for half an hour; drain, put it in a saucepan, add a small onion cut in two, a couple of the coarse stalks of celery, half a turnip, salt and pepper; pour in three cups of water and three cups of milk, let it come to the boil, set back where it will simmer until the vegetables all are soft, then strain through a wire mashing as many of the vegetables through as possible. Return the soup of the saucepan. Add a cup of milk with two well beaten eggs in it and cook gently over the fire until it thickens stirring all the while. Serve with sniffets of fried bread.

POACHED EGGS WITH TOMATO SAUCE.—Carefully poach your eggs. Toast some thin slices of bread, butter them and spread on each slice a little anchovy paste; lay the toast on a hot dish and put an egg on each slice. Have ready some tomato sauce, made by stirring a can of tomatoes with an onion and a few whole cloves, pepper and salt. When they have cooked strain through a sieve, thicken with a good lump of butter rubbed into a tablespoon of flour. Pour this sauce around the eggs and serve at once.

POTATOES BAKED WITH CHEESE.—Cut boiled potatoes, while still warm, in neat, medium-sized pieces; cover them with hot milk, and add salt, white pepper and a little butter for seasoning. Simmer in the milk ten minutes, then fill a shallow baking dish with the stewed potatoes, add a top layer of grated crumbs and cheese and bake a delicate brown.

BEEF LOAF.—Chop three pounds of raw lean beef very fine, add to it two cups cracker crumbs, two eggs, salt, pepper, a cup of milk. Grease a deep bread pan, pack the beef in it and bake; when done turn out onto a dish and serve with tomato sauce.

OYSTER FRITTERS.—Make a batter with a pint of milk, an egg, salt, and flour enough to make it the proper consistency; half a teaspoon of baking powder mixed with the flour. To this add a pint of chopped oysters and fry by spoonfuls in boiling lard.

BROWN BUTTER FOR FISH.—Cook two large tablespoonfuls of butter until it is brown, then let a few sprigs of parsley cook in it for a few moments, skim out the parsley, add a squeeze of lemon juice to the butter and pour it over broiled fish.

TRIFLES.—Cut six small sponge cakes in slices, lay them in a pudding dish, make them soft by pouring either a little sherry or sweet milk over them, spread on them two spoonfuls of jam and pour over a cold custard made of a cup and a half of milk, the yolks of two eggs, sugar to sweeten. Beat up the whites to a very stiff froth, sweeten slightly, heap on top of dish and serve.

EVOLUTION.

SOME VIEWS ON THE ORIGIN OF ORGANIC FORMS.

A paper was published in the *Literary Digest* some time ago, by a Mr. Keep, expressing serious doubts in regard to the evolution theory, to which Prof. Joseph Le Conte makes the following reply in the August number of the *Overland Monthly*: "It has been truly said that in order to criticise any theory profitably, it is necessary, first, not only to understand it, but to sympathize with it. It is certain that Mr. Keep has not been able to place himself at the stand-point of modern thought on the subject of evolution. His point of view is pre-Darwinian. His objections have been already discussed and disposed of. I cannot, therefore, take up these difficulties seriatim. All I can do is to clear up some fundamental misconceptions concerning the origin of life and the origin of species. The theory of evolution is not conditioned, as many suppose, on its ability to explain the origin of life—to imagine so is to misunderstand the true function and domain of science. The domain of science includes only *secondary* causes or processes by which things come about. Or, if we like it better, we may define it as the modes of operation of the First Cause. We trace these processes as far back as we can. If we find a limit, that does not invalidate the previous explanation nor have we any reason to conclude that where our knowledge stops natural processes stop also, and supernatural methods begin. Suppose we accepted the earth as it now is, and knew nothing of how it became so, still there would be a science—physical geography—which studied the laws of its forms and forces. When we learn that the earth has gradually, through an immense lapse of time, become what it is, then we study the laws of this gradual becoming, and we have the science of geology. We may be able to go no farther, we may not be able to imagine, even, how the earth originated, but this does not invalidate the science of geology; nor do we imagine that because our knowledge ceases, natural processes cease also at this point. So it is in the matter of the theory of evolution. The fact of not being able to explain the origin of the different primal forms, does not invalidate our reasoning; neither do we suppose that because we cannot explain the supposed primal forms, they came by miraculous process. By profounder study and greater knowledge we now see reasons for tracing the organic kingdom back to one primal living form of simplest structure. How this primal form originated we do not know and cannot imagine; still we conclnde that it came by a natural process. But the essayist assumes: (1) That it did not come by natural forces, and a natural process, for the same forces would produce similar results now; but this never occurs, therefore the origin of life must be supernatural, and (2) if the origin of the first life was supernatural, then it is probable that the origin of each subsequent kind of life (species) was also supernatural. To the first of these propositions—it is true that every attempt to generate life *de novo* has failed. I believe it will always fail. But the complexity of the problem is so great that any number of failures is not sufficient to convince us of its impossibility. It is evolution itself that makes its impossibility certain. Evolution does not go backward, and begin again at its starting-point. It moves ever forward in some direction. In evolution golden opportunities come but once. For example, supposing man originated by evolution from some lower form of animal; if he were to-day destroyed, there is no possibility that he would be reformed by evolution from any existing animal. No existing form of animal is on its way manward. So, also, supposing life to have originated from dead matter, and physical or chemical forces, if life were swept away to-day from the face of the earth there is no possibility that it would be relighted by any natural process, *i. e.*, it would not be relighted at all. The golden opportunity of favorable conditions is past forever. The conditions under which so wonderful a transformation could take place are so complex that they could occur but once in the history of a planet. Nor is this law peculiar to the living kingdom. The same is true of the inorganic world. The formation of elements, even by natural process, can take place but once in the history of a planet. As to the second proposition, viz., that if life originated by supernatural process, then, also, all subsequent transformations of forms of life were also supernatural, we would ask the essayist to push this proposition to its logical conclusion. He, doubtless, believes that matter originated by supernatural means; therefore, according to his logic, all subsequent transformations of matter are also by supernatural means. On this view what becomes of our science? The essayist says that the conclusions of evolution are so contrary to common experience that the intelligent mind hesitates to accept them. This is a most extraordinary statement. Does he mean that the miraculous origin of species is most in accordance with common experience? Are there any forms of any kind—organic or inorganic, living or dead—that did not, as far as we know, come by a gradual process of transformation? Soil was once supposed to have been made at once as a clothing to cover the rocky nakedness of the newborn earth, and to afford a foothold for plants. Now we know that soil is naught else than the result of the rotting down of rocks. In fact, all inorganic forms, without exception, and all organic forms, so far as common experience extends, came by natural process. Not a single case ever fell under common experi-

ence in which any form, organic or inorganic, living or dead, came by any other process than a natural one. Mr. Keep has been able to cull some hard nuts for evolutionists to crack. The elephant and the whale are acknowledged to be extreme types, the origins of which are very obscure; some steps of the transformation are indeed known, still many gaps remain. But is the theory of miraculous creation any better or half so good in this regard? Remember that science is a study of processes. Is it not evident that any natural process, however strange the result, is more scientific, more in accordance with common experience, than a supernatural origin?"

CUBAN HYGIENE.—A movement is on foot for the establishment of a Society of Hygiene, in Havana, Cuba.

AMERICA LEADS.—Brazil and Mexico have adopted the American locomotive on their railways, and many other countries are following their example.

HEAVY WOOD.—Of the 413 species of trees in the United States sixteen will sink in water. The heaviest is the black iron-wood of Southern California.

MEXICAN ROADS.—In the last ten years the railroad system in Mexico has increased from 300 to 6000 miles, and fully 4000 additional miles are contracted for.

THE WORLD'S BOTTLES.—To bottle the fluids of one kind and another that are consumed in this world requires an annual output of about 8,850,000,000 bottles.

WINE FAILURE.—The wine crop on the Rhine, Moselle, and the Palatinate is said to be a complete failure, owing to the long frosts which occurred early in the season.

DUST AND CONSUMPTION.—Dr. Praussnitz has found tubercle bacilli in the dust of a number of compartments of railway carriages in Germany which had been occupied by consumptive patients.

BRAZILIAN COAL.—Coal equalling that of the finest Lehigh Valley grade, has been discovered in Brazil, the veins being from four to twenty-five feet in thickness. The mines are situated at and near Sonora.

COALS TO NEWCASTLE.—The demand for American screws is so great in England and Germany that a screw company of Providence has established a branch factory in Leeds, England, and will put up another on the Continent.

LANDLORDS' LIABILITIES.—Landlords in England, the courts have held, are liable for damages in case of disease of tenants from defective drains, etc., on condition that the landlord had warranted the premises to be in good sanitary condition.

IMPORTANT PROVISION.—The notification of infectious disease is making fair progress in England. Fifty-five "authorities," with a population of over 6,000,000, now require measles to be reported; whooping cough is notified in 14 districts. It is now suggested that influenza, or it appears the grip, be included as within the notification act.

NEW EXPLOSIVE.—The new explosive called ammonite is probably the most useful and reliable yet made. It has great power, is free from danger in manufacturing and in use, and recent tests made with it in England have resulted in the railroads taking it for transportation without the usual restrictions pertaining to explosives. It is not injured by exposure to the air and will not decompose. Its ingredients are a mixture of 81½ per cent. of ammonium nitrate and 18½ per cent. of mono-nitro naphthalene.

MEMORIAL PRESCRIPTION.—A St. Petersburg lawsuit is attracting much attention. The defendant is a prince, whose wife died from the effects of a too powerful medicine which the family doctor, one of the best known physicians in the city, had prescribed for her. The widower, instead of causing texts of the Holy Scriptures to be sculptured on the tomb, has caused a fac-simile of the fatal prescription, with the doctor's signature, to be engraved on the marble tomb just below the line giving the date of the death of the princess. The doctor is now appealing to the courts of law to have the objectionable inscription removed on the ground that his practice is injuriously affected thereby.

SPEED OF BICYCLES.—The *Kolnische Zeitung* gives an account of some interesting experiments which were tried by Major Brix, the commander of the Militar-Turnanstalt in Berlin, in order to test the speed of bicycles as compared with that of horses, for the purpose of conveying despatches. The distances attempted were, from Straussberg, just under twenty-four miles, and from Eberswalde, thirty-two miles. In the latter journey two cavalry officers rode against two infantry officers mounted on bicycles. The latter accomplished the journey in 215 minutes and 210 minutes respectively, while the two lieutenants on horseback arrived at their destination seven minutes before the first bicycle rider. In the shorter distance the same result was obtained, the riders arriving a few minutes in advance of the bicyclists. In both cases the cavalry officers only rode at a gallop for the first fifteen minutes of the journey, while the bicyclists went at full speed all the way.

Exhaustion

Horsford's Acid Phosphate.

The phosphates of the system are consumed with every effort, and exhaustion usually indicates a lack of supply. The Acid Phosphate supplies the phosphates, thereby relieving exhaustion, and increasing the capacity for labor. Pleasant to the taste.

Dr. A. N. KROUT, Van Wert, O., says:
"Decidedly beneficial in nervous exhaustion."

Dr. S. T. NEWMAN, St. Louis, Mo., says:
"A remedy of great service in many forms of exhaustion."

DESCRIPTIVE PAMPHLET FREE.

RUMFORD CHEMICAL WORKS,
PROVIDENCE, R. I.

BEWARE OF SUBSTITUTES AND IMITATIONS.

CAUTION:—Be sure the word "Horsford's" is *printed* on the label. All others are spurious. Never sold in bulk.

BUSINESS NOTES.

HORSFORD'S ACID PHOSPHATE

For the tired brain from over-exertion. Try it. Dr. W. W. Blackman, Brooklyn, N. Y., says: "I am very much pleased with it in seasickness. Several cases have been brought to my attention where it afforded prompt and entire relief."

Subscription $1.00 per year. Now is the time to subscribe.

ORIGINAL. No. 18.

Plum Roll

BY MRS. S. T. RORER,
Principal Philadelphia Cooking School.

Add one teaspoonful of Cleveland's baking powder and a half teaspoonful of salt to one pint of sifted flour. Sift again. Rub in one tablespoonful of butter, add sufficient milk to make a soft dough. Roll out, sprinkle with one cup of chopped raisins and a half cup of chopped citron. Dust with cinnamon, roll up and steam for thirty minutes. Serve warm with hard sauce.

Use only Cleveland's baking powder, the proportions are made for that.

The most healthful leaven is carbonic acid gas from pure cream of tartar and soda. It is the only leavening power of Cleveland's Baking Powder. That is why Cleveland's is perfectly wholesome, leavens most and leavens best.
Try it, Cleveland's.

25 CTS. PISO'S CURE FOR CURES WHERE ALL ELSE FAILS. Best Cough Syrup. Tastes good. Use in time. Sold by druggists. CONSUMPTION 25 CTS.

PURE PEPSIN

In Powder and Scale.
MANUFACTURED BY

ARMOUR & COMPANY, Chicago.

Guaranteed free from adulteration or make-weights; excellent physical properties and high digestive power.

Under similar conditions, **ARMOUR'S PEPSIN** will exhibit greater activity than any other pepsin now before the profession.

The Manufacturers will be pleased to supply members of the Medical Profession with samples of their pepsin, and with full details regarding digestive strength, if desired.

TO ADVERTISERS.

It is now nearly seven years since the AMERICAN ANALYST began its mission as an advocate of pure food and an opponent of sham products. The history of its labors in that field, even if confined to a reviewal of the success it has achieved in exposing and defeating unscrupulous schemes involving risk to the health and depletion to the purse of the public, would require greater space to rehearse than is available within the limits of this page. As we have heretofore had occasion to explain, in relation to the purposes of this journal, humbugs seeking to enrich themselves through the sale of high-sounding specifics for various human ailments, are subjected to the crucial test of thorough chemical analysis of their goods; and where the latter, as too frequently occurs, prove to be frauds, the facts are placed before our readers in order to save the public from further unconscious imposition. The AMERICAN ANALYST, in addition to the warfare it wages against that species of malefactor, co-operates regularly with the Boards of Health of this and other cities in efforts to secure sanitary and food reforms through organized efforts, and it is conceded to be the only popular medium through which those bodies can bring their purposes and action intelligently before the general public. Reaching as it does all classes—manufacturers, merchants, physicians, chemists, and private families—all over the land, its influence is exerted over a vast radius, producing results as visibly marked as they are wide-spreading. The scope of this journal, however, is not limired to the missionary work above described. Its varied contents cover almost the entire field of scientific as well as social progress, and each yearly volume constitutes a compendium of current facts in nearly every department of knowledge such as can nowhere else be obtained in such comprehensive shape and so cheaply. In this relation we take occasion to publish here a few extracts from a large number of similar compliments that we have received from strangers as well as from our regular patrons. A New Haven editor writes: 'As a newspaper man, and one with a strong, active instinct for good miscellany matter, I want to congratulate you on your publication. The ANALYST is certainly a unique and valuable periodical, and I feel sure that if you press its sale you will gather in thousands who are waiting only to see it before subscribing." A London editor writes us: "I have just seen your excellent paper for the first time, and I am quite delighted with it. I wish you would exchange it for my magazine." A New York journalist, one of the most famous in the profession in America, bore down upon us with the following unexpected praise: "I cannot refrain from congratulating you on the ANALYST. Its brainy suggestions make it one of the most welcome of my exchanges." A well-known scientist says, in the course of a letter on other subjects: "Part of my leisure this summer has been devoted to cutting up my files of scientific papers. It may please you to know that I was astonished to find how perfectly you have kept the ANALYST abreast of scientific thought. It is indeed a valuable paper, and I congratulate you on your success in making it so worthy an addition to technical literature." These extracts will suffice to show the estimation in which the AMERICAN ANALYST is held by experts familiar with its purposes and methods. It is essentially a paper for the family, and with the low subscription price of only one dollar, it ought to find regular and welcome lodgment in every household in the United States.

THE QUEEN'S PRIZE SCHOOL OF HISTORY.

About two years ago the publishers of THE CANADIAN QUEEN added what has proven to be a very popular and successful feature to their publication in establishing their Prize History School. It has offered competitive examinations in English, Canadian and American History, giving valuable rewards to those making the most correct answers. During this time there have been added the names of over forty thousand new subscribers to their books. Rewards have been made by THE QUEEN which have cost them in cash over ten thousand dollars. THE QUEEN'S Prize School of History has received the sanction and support of the clergy, press, and, in fact, of the best people of the Dominion of Canada. The following, taken from a leading daily newspaper, expresses an opinion which is universal:

A HANDSOME PRIZE.

AN EVIDENCE OF WHAT A GENUINE MAGAZINE COMPETITION OFFERS.

"On Friday there arrived from Toronto, for Miss M. Hora, a handsome Shetland pony, harness and cart, being the first award in the Royal Quilt Competition of THE CANADIAN QUEEN magazine. It attests the genuine nature of the magazine's contests by its excellent condition and value. THE QUEEN has frequent competitions and has made innumerable awards, displaying a generosity quite surprising to those who have had experience of the limited field for Canadian journalistic enterprise. But THE QUEEN has been a success as a business venture from the start, and is growing in literary excellence steadily. It covers the field of fashion, as well as light reading; talks to the household, the young, and, indeed, all home classes. The competitions have been used to assist the introduction of the magazine, for where it is introduced it is quite certain to remain a monthly guest. The leading prizes have been made, as instance this latest to Kingston, while many smaller prizes have rewarded the moderately successful among competitors. THE CANADIAN QUEEN is truly royal in its ways."—*The (Kingston, Ont.) Daily British Whig*, June 27th, 1891.

QUESTIONS IN AMERICAN HISTORY.

1.—Give the names of the early navigators who it is claimed by historians first discovered America.
2.—From whom has America taken its name?
3.—What class and nationality first settled Virginia? New York? Massachusetts? Pennsylvania? Maryland?
4.—What action did the Continental Congress of 1774 take and what was the result of that action?
5.—What was the first battle fought in the War of the Revolution?
6.—What nation rendered the Americans great assistance in the War of the Revolution?
7.—Give the names of the committee appointed to draft the famous Declaration of Independence.
8.—What was the date of the signing of the United States Constitution?
9.—After becoming a nation and before the great Civil War, what were the principal conflicts which engaged the Americans?
10.—What was the direct cause of the Civil War? What Generals of the Northern Army have occupied executive positions under the Federal Government since the closing of the War? Who was Commander-in-Chief and who were the principal Generals of the Confederate Army during the struggle?
11.—How long did this War last and what is the computed loss of life?
12.—What can be said to-day of the United States as a nation?

To the *First* gentleman sending the correct answers to the above questions in American History the publishers of THE QUEEN will present **"Majestic,"** acknowledged the **Handsomest and Finest Riding Horse in Ontario.** ("Majestic" is sixteen hands high, thoroughbred, seven years old, and valued at $350.00.) To the *First* lady the publishers of THE QUEEN will present an elegant **Jacket of Genuine Alaska Seal** to be made according to the measurement supplied by the winner. To the *First* boy under sixteen years of age the publishers of THE QUEEN will present a **Little Giant Safety Bicycle,** valued at $75.00. To the *First* girl under sixteen years of age the publishers of THE QUEEN will present an elegant **Music Box,** playing twenty tunes, finely finished and valued at $55.00.

To the gentleman from whom the *Last* correct answers are received before the close of this Competition, the publishers of THE QUEEN will present a **First Cabin Passage to Europe and Return** and **$200 in Gold** for expenses. This trip can be taken by the winner any time before October 1st, 1892. To the lady from whom the *Last* correct answers are received before the close of this Competition the publishers of THE QUEEN will present a **Pony, Cart and Harness.** To the boy under sixteen years of age from whom the *Last* correct answers are received before the close of this Competition the publishers of THE QUEEN will present a **Solid Gold Watch** containing one of the best American movements, and valued at $75.00. To the girl under sixteen years of age from whom the *Last* correct answers are received before the close of this Competition the publishers of THE QUEEN will present an elegant **Solid Gold Watch,** containing one of the best American movements, and valued at $65.00.

ADDITIONAL PRIZES IN ORDER OF MERIT: Silver Tea Services, Ladies' Gold Watches, Silk Dress Patterns, French Mantel Clocks, Portiere Curtains, Toilet Cases, Manicure Sets, and many other useful and valuable articles.

The object of the publishers in offering these liberal prizes is to introduce THE QUEEN Magazine into **new** homes. Answers must be mailed *on or before* November 10th, 1891, and must be accompanied by $1.00 for one year's subscription to THE CANADIAN QUEEN. Prizes awarded to subscribers residing in the United States will be shipped to them **free of duty.** The distribution of awards is in the hands of disinterested persons, and decisions will be based on the correctness of answers. Use your own language in wording the answers. No corrections can be made after your answers are mailed. THE QUEEN is a large, forty-eight page family magazine, especially interesting to ladies and children, and visits regularly **over one hundred thousand of the best homes** in Canada and the United States. The awards in THE QUEEN'S Prize School of History are made strictly with regard to merit, without partiality to persons or locality. The decisions must be accepted as final. If you have never seen a copy of THE QUEEN send six U. S. two cent stamps and receive a late number, post paid, containing letters from those who have received rewards in previous contests.

Address THE CANADIAN QUEEN, PRIZE SCHOOL OF HISTORY, 58 BAY STREET, TORONTO, CANADA.

OUR GREAT OFFER

TO SUBSCRIBERS

TO THE

AMERICAN ANALYST.

We will send the **ENTIRE SET OF DICKENS' WORKS,** *in* **TWELVE VOLUMES,** *as here described, all postage prepaid by ourselves, also* **THE AMERICAN ANALYST** *for* **ONE YEAR,** *upon receipt of* **$1.50,** *which is only* **50** *cents more than the regular subscription price of this paper.* Our readers, therefore, practically get a set of Dickens' works in twelve volumes for only **50** cents. This is the grandest premium ever offered. Up to this time a set of Dickens' works has usually been $10.00 or more. Tell all your friends that they can get a set of Dickens' works in twelve volumes, with a year's subscription to **THE AMERICAN ANALYST** for only **$1.50.** Subscribe now and get this great premium. If your subscription has not yet expired, it will make no difference, for it will be extended one year from date of expiration. We will also give a set of Dickens', as above, free and post-paid, to any one sending us a club of three yearly subscribers.

TABASCO PEPPER SAUCE,

OR LIQUID PEPPER.

Is simply the Pulp of the Ripe Pepper Extracted by Pressure.

The seed of this Pepper was obtained from Central America, and by careful cultivation in Louisiana for many years has been so improved in strength, flavor and aroma, as to have become a new variety of Red Pepper, superior to all others. The pulp is so handled as to retain all the flavor, strength, aroma and color of the ripe fruit, and to keep unimpaired in any climate. It excites the appetite, promotes digestion, and is pronounced by connoisseurs to be the finest condiment in the world. For medicinal purposes it recommends itself by its purity, strength and diffusible form.

Manufactured by E. McILHENNY'S SON,

NEW IBERIA, LA.

For Sale by all Wholesale Grocers.

NATRONA BI-CARBONATE OF SODA.

(ABSOLUTELY PURE.)

NATRONA TRADE MARK SODA

The nature of the raw material from which NATRONA BI-CARBONATE OF SODA is made—viz., kryolith, a mineral containing *pure sodium*—insures a purity and uniformity of product which cannot be obtained from any other known material. In making BI-CARB. SODA from any other raw material, the use of sulphuric acid is a necessity, but none is used in any part of the process of making NATRONA BI-CARB.; hence its entire freedom from the slightest trace of arsenic, which is always present in ordinary soda. Its absolute purity and entire freedom from all traces of *sulphate of soda*, common salt and other impurities, render NATRONA BI-CARB. NEARLY TASTELESS, and being bolted through the finest bolting-cloth, insures the finest stage of division.

To these indisputable facts the attention of CONSUMERS of soda is specially called. They are IMPORTANT, and should influence both those who use and those who sell soda, to buy and sell NONE BUT THE BEST.

The NATRONA BI-CARB. Soda is kept in stock by almost every wholesale druggist and grocer throughout the United States, of whom it may be ordered.

Natrona Bi-Carb. Soda is unequaled by any other brand of English or American Manufacture.

FOR SALE BY

ACKER, MERRALL & CONDIT, and PARK & TILFORD.

To Subscribers, Readers and Advertisers.

SUBSCRIBERS' attention is called to the great variety of interesting and instructive subjects treated in this number. We respectfully ask the co-operation of our subscribers in extending our Subscription list, which will enable us still further to increase the value of the AMERICAN ANALYST to them.

The CASUAL READER is specially requested to examine our liberal premium offer.

ADVERTISERS who do not know of this Journal already, are respectfully referred to article headed "A Business Benefit."

ALL are kindly requested to peruse this number thoroughly.

The AMERICAN ANALYST can be had at any news stand in the United States. Any newsdealer will take orders for it, the American News Company being our wholesale agents. All postmasters will receive subscriptions.

RHEUMATISM AND NEURALGIA

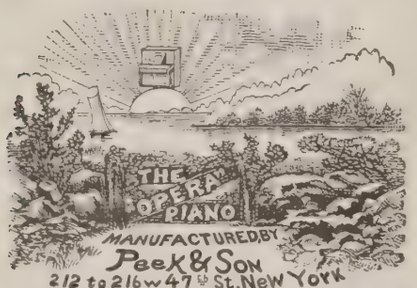
are being constantly cured by Robinson's "Sura Cura," a positive antidote for all impure states of the blood. Price, $1.00, sent by mail. Send for circular.

R. W. ROBINSON & SON,
184 Greenwich St., N. Y.

DO YOU KNOW THE **DANGER** OF USING SOAP?

IF YOU ARE GOING TO THE COUNTRY, DO NOT FAIL TO READ THE FOLLOWING.

We do not mean soap made from proper material; and when we tell you that about ninety-nine per cent. of Toilet Soap is made from refuse fats gathered from tenement houses, hospitals, butcher shops, and from cattle dying of disease or during transportation, you will, we believe stop and think. Putrefactive changes have taken place in most of this material, as it is mixed with lean meat, blood, bones, sinews, etc. There is at least *one* soap that is made wholly from vegetable material—OLIVE and PALM OILS—and that is



VELVET SKIN SOAP.

It will keep the skin soft and in a healthy condition, as no animal fats are used in its manufacture. Nothing in one's personal outfit is quite so satisfactory as a thoroughly reliable Toilet Soap. We are confident that a trial of this article will insure its continued use. If the dealer does not keep it, do not take any other, but require him to order it for you, which he can do readily. **Otherwise, send to us direct.**

MANUFACTURED BY

LIFE INSURANCE.

It seems to be the practice of life insurance companies to confine all information concerning themselves to the columns of the so-called insurance press. As the circulation of these insurance journals is strictly confined to the narrow limits of the companies' offices and waste baskets, with the exception of such copies as may contain a particularly venemous attack upon some company, and which are marked and mailed where they can do the most good, the great mass of the public has to depend otherwise for all information upon such circulars as the companies have carefully prepared for them, and the more or less vague statements of their hosts of canvassers. Life insurance is an important adjunct of modern social life, and more should be known about it. Any company which does its business honestly and honorably surely can have nothing to gain by concealment; while, on the other hand, there is everything to be gained by the most open discussion of the whole subject. The question naturally arises, Have the companies nothing to conceal? Is everything conducted fairly and squarely? When we read in the daily papers that one large life insurance company is daily accused of everything else but honest dealing; that they employed an important official for many years, who has for years been making charges of dishonest management, and added weight to these charges by openly asserting that the committee of the board of trustees of that company appointed to investigate his charges was a whitewashing committee; and to clinch it wrote letters to the public press, and stated in interviews, that there were other and more serious charges not made yet. When, in addition to all this, we see that only after several years and reiterated charges this official was finally dismissed from the service of the company, we seriously question if any further official action can regain lost public confidence. There has not been time yet for the dismissed official to have his say, and that he has a gun loaded to the muzzle there can be no doubt. In the meantime, other life insurance companies are looking on, enjoying the fun. While the public attention is attracted to their competititor, they think they are safe from too close watching or newspaper comment. They understand the case fully, serious charges have been made against a competitor—will there be similar or worse charges against themselves next? Have they any glass in their houses which they need fear will be broken? How many of our large life insurance companies would like a thorough, capable and honest accountant to go through their accounts and books? How many would be able to stand by cooly and have their dividend systems or investments thoroughly examined? Life insurance companies handle vast sums of money; they receive it from many people and pay it out to a few, and generally to women, who, when in their distress at the loss of a beloved one, are not so apt to examine closely the correctness of the account. They look for a specified amount, and if paid that with reasonable promptness expect nothing more, though they may be justly entitled to double and treble the amount. The man who has denied himself for years that he may be able to lay up something in the way of insurance for the loved ones he leaves behind him finds himself suddenly confronted by a financial disaster, he must have money at all hazards. There is nothing so easy as to sell his policy to the company, for he argues, when over this trouble he can soon provide a new insurance. Do the officers of the company seeing his pressing need and his readiness to take anything, give him all he is justly entitled to? The life insurance company is a soulless corporation and often its officers have been found just as soulless. They have the handling of large sums and no very close scrutiny is had upon their methods. A man takes a policy and pays all he is asked, and when he dies his widow is left to the mercy of a so-called adjuster whose sole business in many of these companies it seems to be to find all the flaws he can in the proofs of death that have been filed with the company, and by inuendos, and covert threats try to cut down the amount that should be paid without question. All this is wrong—we have already spoken of the fact that most of the life insurance companies confine any published information to the insurance press. Why is this? Is it because they are afraid that if they do not liberally support the insurance press they will be attacked and cannot stand the attack? Why is all the life insurance advertising in the daily press confined to a bare statement of the names of the company, the officers and the trustees with the exception of perhaps once a year, a so-called statement which is all Greek to the majority of the public. If the life insurance companies desire the confidence of the public, and without that they cannot get the business, they must be more liberal in imparting information, in educating the public up to their methods; they must so treat a man that it will cease to be a common by-word that to leave a life insurance to your widow is to leave her a law suit. Perhaps they think they have all the business they can get. It may be so under present circumstances, but if the great mass of the public could feel that the companies were doing business honorably and above board there would quickly be a large increase of policies over the beggarly proportion now carried. Our population has increased, but life insurance has not increased with it. It should have increased largely.

UNDESIRABLE CITIZENS.

An average of a million immigrants a year have landed in the United States during the past five years, of whom fully one half were of the lowest grade of the laboring classes. A large proportion could neither speak, understand, nor write English—they were Italians, Portuguese, Hungarians, Russians, Poles, and Scandinavians. Of the Italians, the Portuguese, and the Hungarians, the greater proportion are in no degree qualified for homes in this republic; they are of baneful nature and vicious methods of life. They most injuriously cheapen labor and cause disorder, provoke turbulence, and disturb the general peace and good order. The German communist and Russian nihilist are incendiary and insurrectionary, in measure mischievous and dangerous, but they are not assassins of the Mafia stamp, nor do they trouble the fields of labor to incite strikes or influence the laborers to riot and armed violence. To swill with beer and foam, to fume as they quaff fiery spirits, is the extent of their vaporing, the extremity of their disorderly demonstrations. They spill no blood, rarely destroy property. They do not make good citizens, and, therefore, are not desirable and are not wanted or welcome to this country. The Chinese and the natives of Asia are intolerable; but the hordes from Europe are immeasurably worse. The Chinese are inhibited from citizenship and can not become voters, while the courts grind out the refuse and scurf of Europe in naturalization, and invest with the elective franchise the scourings which should be

committed to the prisons. The continuance of the evil will virtually disfranchise the mass of intelligent, earnest citizens by the overflowing vote of corruptionists, as they purchase and dragoon their bought and submissive bands and gangs at the polls to force and win the infamy of victory. Congress should take the matter in hand and put a stop to this indiscriminate, pestilent immigration. A radical reformation of the law governing immigration is absolutely demanded.

THE INCANDESCENT LIGHT.

The growing adoption of the electric light in private houses as well as in places of public resort renders it of interest to briefly elucidate its precise nature, and to dissipate certain obscurities which obtain in regard to it. It "burns" steadily is a very common expression. But "burning" is the very thing it does not do. There is no "burning" without oxygen; and the incandescent lamp is first exhausted of air, and then hermetically sealed. What in rough and ready language is called "burning" is only the white-heat glow produced by the resistance which the fine carbon filament in the lamp offers to the passage of the electric current. The copper wire through which the currrent "flows" from the generating machinery is also the medium through which the current returns to the machinery. If the wire were continuous, there would be no sign of the current, for, the copper being a good "conductor," the current flows through it without resistance. But for lighting purposes you sever this wire, as it were, and the non-conducting carbon filament inside your lamp is but an obstacle through which you compel the current to pass in its race from the dynamo and back. The resistance offered by the carbon produces the white-heat glow. But, as already said, to call it "burning" is inaccurate. The friction between two substances produces an analogous phenomenon; but only analogous, for the sufficient reason that electricity is not a substance, but only a special form or manifestation of force. There being no "burning" there can be no contamination of the air in the room. The substitution of electricity for gas is, therefore, a hygienic improvement of incalculable value.

AN EVAPORATED PHENOMENON.

The famous overflow of the Colorado River in San Diego County, California, on June 27, does not seem to have produced the permanent topographical changes in that region that were expected. Information from Salton, of the date of August 24, states that little by little the Salton Lake sensation is dwindling away, and the great inland sea is becoming a mere film of water over the surface of the salt basin. And it seems that even that is nothing new. There always has been a lake in the Salton basin, and the water is only four inches deeper than it has been to a certainty every August since 1870, and probably every August for many years before that. Recently there were thunder storms and cloud bursts in the southern counties, and the Salton Lake boomers declared that such things were unprecedented, and that the presence of the great body of water had changed the climate. Thunder storms and cloud bursts are in fact regular August occurrences south of Tehachopi. The rainy season of Arizona is July and August, and in those months great masses of rain-laden clouds come trooping across the desert and break against the mountains that form a bulwark between the San Joaquin Valley and the Mohave plain. These cloud masses are called 'Arizona runaways," and are said to be as familiar to southern Californians as are the names of the months in which they make their appearance. An exploration of the much advertised lake made, during the last week of August, showed that the alleged sea had then evaporated to only a strip of water about 300 yards wide surrounding a great body of salt. The water over the salt bed was less than four inches deep. The overflow from the Colorado brought in the amount of water represented by that four-inch film over the basin. When the lake was at its deepest the area covered was thirty miles by ten, and the greatest depth in the edge strip was four feet. The conditions in the basin are the same as usual, except that there is a shallow film of water over the surface instead of just beneath the crust, and that, it is expected, will soon disappear by evaporation, leaving perhaps a strip of 300 yards wide and twenty miles long. All the excitement was due to the fact that the water in the Colorado was higher than usual, and more of it than was customary flowed through the break and over the desert.

MODERN LIGHT.

A GERMAN OPINION ON ELECTRICAL ILLUMINATION.

From Grecian mythology we learn that Prometheus stole fire from heaven where the gods guarded it jealously. Prometheus? Presumably some great discoverer, the Edison of a prehistoric age. What he then achieved may have created just as much admiration and wonder as we experience at sight of the incandescent American lamps. How have these wonders been achieved? Even in old Homer's time tallow candles were a little known luxury, and Ulysses returning to Ithaca, to the halls of his fathers, surveys the wine-stained countenances of his companions in the ruddy glare of flickering chips and bundles of twigs. How different now! A cascade of brilliant rays radiate from flowers of fabulously wondrous beauty, with incandescent lamps in their interior, falling on facets of crystal glass, on mirrors, on gold frames, on marble statuary, and porcelain figures, covering them all with a halo of splendor. We are in the age of electricity! Electricity! The word suggests a secret revelation of the wonders that surround us—a dream of new powers with which science will invest us; a new authorization of man to assume control over nature, and to mould the conditions of his existence into richer and more attractive forms. And now, how do we produce this uncertain, immaterial substance that can dazzle like the sun and strike like the lightning? Its origin is as incomprehensible as its character. The mere contact of two metals produces electricity, the friction of two bodies upon each other, whether they are hard like glass, or fluid like water, the heating of certain mineral crystals, the revolution of one glass disc upon another under certain prescribed arrangements; all these generate electricity. Everywhere in earth, air, fire, and water, we are confronted with the evidence of the presence of this uncertain force, which appears only to disappear in the great body of the all-mother earth from whose womb issues all that lives or breathes: to whose womb whatever has life, or force, or energy, must sooner or later return. For industrial and illuminating purposes, electricity is produced by means of dynamo machines. The fundamental idea of these wonderful contrivances is that wire spools are maintained in revolution past strong magnets. Whenever the spools approach or withdraw from the poles of the magnet, a current of electricity originates in the wire. To keep a wire spool revolving past a magnet would be amusing child's play if there were no hindrance, and electricity might be generated very cheaply in a continuous current; but with the increase of the current in the wire spools, there is generated a corresponding antagonism between the magnetism of the iron magnet and the electricity of the wire. The wire strives to go over the shaft, but to enable it to do so, a force is required proportionate to the force of the electricity generated. This required force is supplied by motors, steam engine, wind mill, water wheel, or other power. In a central station for lighting a city or quarter of a city, we witness a whole series of direct transformations of power from one form into another. Coal is burnt, and the heat thus generated converts water into steam, and gives the steam elasticity. This elasticity operates the machine, precisely as men or horses might, in fact, it performs labor; and this labor employed in revolving the wire spools, generates or is converted into electricity. The whole series of processes may be reversed, and electricity converted into heat for cooking, or into power for operating machinery. Endless are the applications of which electricity is susceptible, for electricity, heat, light, steam, the chemical union of elements are all intimately related; they are capable of performing labor precisely as labor is required for their production. Light, although seemingly so unsubstantial and powerless, is labor, and requires force to generate it as much as wood chopping or verse making. Every ray of light that vibrates in space is as full of force and energy as the axe of the woodcutter in its swing. Every ray that comes to us is the product of chemical labor applied to distant stars by elements such as oxygen, carbonic acid, etc., in the fierce tumult of chemical union and decomposition. Even to this day savages generate fire by the sweat of their brow through the rapid continuous friction of two bits of wood. The day will assuredly come in which electricity will be generated directly from the heat of burning coal without the intervention of steam or dynamos; something has, indeed, been already achieved in this direction. Berlin may be said to be the birthplace of dynamo machines, as well as of the electric railway, and of other achievements in electro-technology in which department the illustrious name of Siemens is unrivaled. The Berlin Electric Works include five central stations, in which the needed electricity for the supply of the city is generated. In March, 1889, there were in the capital 3,714 arc lamps and 62,876 incandescent lamps in operation. For motor and illuminating purposes, the five central stations distribute about 8,000 horse-power which will shortly be increased to 18,000. Eighteen thousand horse-power! What an enormous force. To realize its immensity one requires to institute comparison with a past like that of Egypt, whose mighty pyramids were erected by human hands. Such work would be mere child's play, comparatively, in this age. Why, Berlin's electric force at this moment performs labor equal to that of 70,000 men. The existing steam-power of the world is estimated at 6,000,000 horse power, equal to 50,000,000 laborers. Where now would be the progress in our culture if we were dependent on muscular force? Labor is capable of producing not only physical light, but, being economized, may be converted into spiritual or intellectual light; thus machinery, not merely economizes production, but ministers to the material and intellectual progress of the race.—*Vom Fels zum Meer.*

LIGHTNING.

THE MODERN METHOD OF SECURING PROTECTION.

Recent scientific study has swept away some of the old notions about conductors. The method now considered the best for the protection of buildings is to provide a metal roof, with an ample number of metal conductors leading to the ground, which will receive and carry off the electric bolts from the clouds. Copper is the best material, but tin or iron will answer the purpose; and I always suggest the placing of the conductors at the corners of a building, so that all parts will be equally protected. Though rods may be used, rain spouts will answer the purpose equally well. The physical laboratory of the Johns Hopkins University is protected from lightning by the roof and spouting. You can safely class all patented lightning rods as being of little value beyond conducting rods that any man can put up himself, because the simple principle underlying all is that the lightning will follow the best conductor. The idea so largely adopted in the erection of lightning rods, that a small band of glass will prevent the electric current from passing to a better adjacent conductor, seems playful. While it is true that light-

ning is attracted to an elevated point or angle, when you cast your eyes over a city like Baltimore, and see the large number of such points and angles, the use of pointed rods fades into insignificance as compared with the method of roofing with a good conductor. This was illustrated by the incident of lightning striking the great monument in Washington several years ago. The monument is capped with a piece of aluminum, which has metallic connection with the ground by means of the iron work of the interior, but the lightning did not strike the top of the cap. It descended to some copper mixed in the side of the pyramidal top, some distance from the apex, burst a portion of the stone, and, running along the copper into the interior, leaped without any metallic connection to the iron framework and passed to the ground. A framework of copper rods, covering the angles, and crossing the sides of the immense cap, was recommended by me at that time for the future protection of the monument, and has probably been constructed. The ground connection was to be through the internal iron work spoken of. Somewhat similar to these methods is that of the Peabody Library. The iron shelving connected with the metallic roof, and resting on a stone foundation which might be shattered by a stroke of lightning, has been connected with the ground by metal conductors, and no danger from lightning is apprehended. Lightning has no fixed portion of a building to strike. The stroke may fall at the centre of the roof, and while it runs along the surface of a body, the body may be broken or crushed by the enormous pressure brought to bear upon it, in the same manner that an explosion of dynamite or nitro-glycerine would cause a fracture. I have some fragments of a church spire struck by lightning, which are bound together in their former relative positions, but exhibiting all the fractures produced by the concussion. There is a vast difference between the quantity of electricity and what is known as electrical pressure. This is illustrated in a simple manner by the compression of the air. A small quantity of air can be compressed to the same degree to obtain as great an expansive force as a large quantity. The quantity of electricity in a stroke of lightning is not nearly as much as passes along almost any electric wire on the street, but the voltage or electric pressure of the street wire is rarely 3,000. A volt is the basis on which the pressure is estimated. The voltage of the lightning stroke is roughly estimated at 6,000,000,000 volts. In addition to this appalling difference, it may be said that the current of the wire is constant and continuing, while the lightning dart is delivered in the one two hundredth part of a second. Such an astounding force is capable of doing many strange things. In speaking of places of safety during an electrical storm, Dr. Rowland said that probably as safe a place as any other would be an iron bedstead, provided the ground connection is perfect—this being in line with the above theory, that the lightning would follow the best conductor.—*Baltimore Sun.*

THE CORK OAK.

A NEW INDUSTRY FOR CALIFORNIA.

Every year adds something to the diversity of the products of Californian soil and climate. No fruit, flower, shrub or tree known to the temperate zone that does not here find a genial abode, while semi-tropical and even tropical products vie with the hardier vegetation of the colder zones in the measure of their lusty growth and generous fruition. And now comes the cork tree to the front to claim its share of public attention as an important source of wealth, for future generations, at least, in this land so favored by nature and so lavish in its rich gifts to man. That it will flourish and produce its velvety bark here in prolific perfection, the evidences of many a tall and vigorous cork oak now growing in various localities in the State prove beyond doubt or cavil. That few among the earlier settlers in California may live to see the production of cork as an article of manufacture and commerce attain any considerable degree of importance may be true; but that it has become the bounden duty of present generations to plant the seed that posterity may reap the harvest, is a proposition that no reasonable man will care to dispute. So far, individual enterprise has estabilised the fact the cork oak (*Quercus Suber*) has here found a congenial home. We have heard it stated that General Bidwell has recently sold, in the San Francisco market, a considerable quantity of cork bark of the finest velvety quality, the product of trees upon his property at Chico. In a recent visit to Ione, in Amador county, we saw a cork tree, raised from an acorn planted thirty-two years ago by Mr. Surface, of that town, the bark of which, on cutting it away, seemed to be of the very best quality of "velvet cork," and would no doubt command a high price in the market. It would appear, therefore, that the soil and climate of California are better adapted to the growth of this tree than those of Spain and Portugal even; for there the first yield of cork bark "is rough, unequal and woody in texture, is called virgin cork, and is useful only as a tanning substance or for rustic work in conservatories, etc." The fact therefore having been demonstrated that the tree will grow in California, and will produce as good, if not a superior bark to that elsewhere found, the question presents itself: What is the duty of the State, through its legislative and executive authority, in the matter of fostering the planting and cultivation of the cork tree? If California is to become the great wine and brandy producing country that it promises to be, the question of the future supply of corks to meet the demand for home consumption alone becomes of the most serious importance. Moreover, the collateral question of creating a new product that is to increase the future wealth of the State adds largely to the magnitude of the subject under consideration. In the six years from 1880 to 1885, inclusive, Spain and Portugal exported manufactured and unmanufactured cork to the value of $23,658,453, beside what was used in home consumption to supply the large demand for wines, etc., produced in those countries. Why should not California take first place in the future in the product and manufacture of this important article of commerce, and so not only keep at home the large amount of money that will otherwise find its way abroad in the purchase of the foreign article, but also reap the harvest of profit that will be derived from its own exportations to supply the always growing demand of the world at large?—*Argonaut.*

HISTORIC HEAT.

SOME HOT DAYS BEFORE HUMIDITY WAS INTRODUCED.

In 1303 and 1304 the Rhine, Loire and Seine ran dry. It seemed as if New York was on fire in 1853. The thermometer ranged from 92 to 97 degrees for five or six days. During the heated term 214 persons were killed of sunstroke. In France in 1718 many shops had to close. The theatres did not open their doors for three months. Not a drop of water fell during six months. In 1773 the thermometer rose to 118 degrees. The heat in several of the French provinces during the summer of 1705 was equal to that of a glass furnace. Meat could be prepared for the table merely by exposing it to the sun. Not a soul dare venture out between noon and 4 P. M. In 1800 Spain was visited by a sweltering temperature that is described as fearful. Madrid and other cities were deserted and the streets silent. Laborers died in the fields, and the vines were scorched and blasted as if by a simoon. The year 1872 was a fearful one in New York. One hundred and fifty-five cases of sunstroke occurred on July 4th, of which seventy-two proved fatal. The principal thoroughfares were like fields of battle. Men fell by the score, and ambulances were in constant requisition. In 1778 the heat of Bologna was so great that numbers of people were stifled. In July, 1793, the heat again became intolerable. Vegetables were burned up and fruit dried on the trees. The furniture and woodwork in dwelling houses cracked and split and meat went bad in an hour. A disastrous hot wave swept through Europe in June, 1851. The thermometer in Hyde park, London, indicated from 90 to 94 degrees in the shade. In the Champs des Mars, during a review, soldiers by the score fell victims to sunstroke, and at Aldershot, England, men dropped dead while at drill. In July, 1876, intense heat began to make its power felt throughout the Middle and Southern States. In Washington the heat was frightful. General Sherman declares that the car rails became so expanded by the action of the sun as to rise up in curved lines, draw the bolts. In one instance the rails burst away from the bolts and left the track entirely.

INDIA INK.—India ink is made from fine lampblack compacted and cemented with glue. The finest black is derived from pork fat. The glue is made from buffalo hide.

ALPINE HOTEL BILLS.—The landlord is writing out the bill with the assistance of the head waiter. "Have you noticed that the gentleman in No. 7 looked at the weather vane every morning during his stay here?"

"Yes sir; every morning."

"Then we'll put down, 'For use of weather vane—three francs.'"

A NEW DEFINITION.—A teacher gave out words for analysis. "Banknote" was one of them, and the teacher's astonishment may be imagined when one young lady brought the following unique analysis: "Bank-note is a compound, primitive word, composed of 'bank' and 'note'. 'Bank' is a simple word, meaning the side of a stream; 'note,' to set down. 'Bank-note,' to set down by the side of a stream."

NEW DISINFECTANT.—A recent discovery, which is the outcome of the investigations of Dr. H. Oppermann, and which he has also patented, is the application of dolomite to antiseptics. The dolomite, after a special preparation, is mixed with a certain proportion of oxide of iron and iron pyrites, and the mixture is employed in the form of a powder. According to the experiments made at the Hygienic Institute, at Kiel, it seems likely to substantiate its reported efficacy.

DESIRABLE INVENTION.—A well known railroad man declares that one of the most useful inventions that can be thought of in connection with operative railroading is one that will automatically take the rear brakeman by the nape of the neck and shoot him back from the train a sufficient distance to protect it, when, for any reason, an unusual stop is made. He declares, as a result of considerable experience with the genus brakeman, that nothing short of this will suffice to make it at all sure that trains will be protected under such circumstances, because nothing short of some such device can compel brakemen to go back a proper distance with the flag or lantern.—*Industrial World.*

A GROOM'S CHECKBOOK.—A young man of fashion in Buffalo, who got married not long ago, did a unique thing A short time before the wedding he bought a new checkbook, and had lithographed obliquely across the face of each check his own name and his bride's maiden name in small letters and under them the word "Married," in bold characters, followed by the day and date of the wedding. The young man has used the checkbook solely for the payment of his wedding expenses—his new clothes, his gifts to the bride and wedding party, the antenuptial suppers, luncheons and river parties, the parson's perquisite, and all the bills incurred during the honeymoon, besides getting the checks cashed for his pocket money. At the end of four weeks from the wedding day he means to stop using these checks, collect all the vouchers, tie up all together, mark the parcel "Honeymoon Vouchers," and lock it up in a strong box, which is not to be opened until the silver wedding anniversary twenty-five years hence.

BRIGHT STORIES.

A STRANGE TEMPTATION.

Herbert Hendon, M. D., was fond of his profession, but he was a good deal fonder of horse-flesh. The tenth year of his London practice found him making a very considerable income; but, grievous to relate, by far the largest proportion of that income found its way, year by year, into the coffers of the bookmaking fraternity.

Never yet had he been a defaulter on settling day, but this had only been rendered possible by ignoring his trades-people's demands. There was no blinking the fact that he was considerably involved and did not see any way of escaping the Bankruptcy Court, save by some great and successful coup.

It was in 1887, just a week before Watts steered Merry Hampton to his Derby victory, that Herbert Hendon entered his consulting room, and rang his bell for the first patient to be shown in. He felt terribly down on his luck, for he had got what he believed to be a splendid tip for the great race, but knew not where to turn for money. He was in anything but a proper frame of mind to do justice to his patients on this particular morning.

However, as the door opened, he pulled himself together, rose and stepped forward with his usual bland welcome.

A young man entered, and, proffering his hand, sank with an air of much lassitude into the chair, to which the doctor motioned him. He was tall and very spare, with hollow chest, and his face an unwholesome pasty color. His breathing came short and sharp, and Dr. Hendon saw at a glance that this was anything but one of his "bread-pill" cases.

He listened attentively as his patient described his symptoms, and then proceeded to subject him to a rigorous examination. To make a long story short, he discovered that Gordon Paston was suffering from a practically incurable disease, and that the only thing to do was to prolong the few short years that were left to him to their utmost limit. He did not, of course, tell his patient thus. He merely hinted that the disorder might grow into something serious unless great care were taken with it, and that he hoped, after the course of treatment to which he proposed to subject him, that he would be able to set him on his legs again. He then wrote out a prescription, gave him a list of foods to be avoided, and expressed a wish to see him again in a week's time, after which he rose from his seat as a hint to his patient to be going, but Gordon Paston still sat on in his chair.

"Dr. Hendon," he said, after a moment's pause. "I hope you will excuse me when I tell you that I know very well what is the matter with me. I know, too, that you, with very proper kindness, have made light of the fatal disease from which I am suffering. I know, from more than one doctor, that it is only a question of keeping me alive for a few years. No, please, do not protest, but kindly hear me out in what I have to say. I do not want to pretend to you that I look with unconcern upon approaching death. Far from it. I am immensely enamored of life, and my capacity for enjoying it is as strong as ever. Now, I hope you will forgive me for the proposal I am about to make. I am a poor man—that is to say, my income is about £300 a year. My tastes are somewhat extravagant, and that is far from sufficient to satisfy them. My little income is derived from an invested £8,000, my absolute property. Now, what I propose to do is to apportion that capital sum to the remaining years of my life, of course with a sufficient margin to allow of my disappointing the undertakers for a bit, and to pay my just debts and funeral expenses. My only sister is married and very well off, so that I feel perfectly justified in leaving as few assets as I like. So you see, doctor, what I want you to do is to give me the very latest date up to which it is possible for me, under the most favorable circumstances, to live. Please do not be afraid of telling me the shortness of my tether, for you see the shorter time I have, the more merrily I shall be at liberty to squander my £8,000."

To say that Dr. Hendon was amazed at the calm calculation with which this man contemplated the near approach of death would be overstating the case. It takes a good deal to astonish a doctor who has been in continuous practice practice for ten years. But it was the first time in his life that a patient had begged him not to hesitate to fix an absolute period beyond which it was impossible for him to live, and he felt somewhat embarrassed at the request.

His patient noticed his hesitation, and said that perhaps he would like to give some further consideration to his case, as the issues were somewhat momentous. He would, if he wished, call again for the verdict the following morning.

This was finally agreed upon, and Dr. Hendon felt relieved at the postponement of what was to him a very unpleasant responsibility. The next day Gordon Paston was again his first visitor and the doctor subjected him to a further careful examination.

He then sat down and faced his patient.

"Your case, Mr. Paston," he said, speaking with deliberation, "is a peculiarly easy one for prognosis. The disease from which you are suffering invariably terminates fatally, as you are aware, and its duration can be predicted with the greatest confidence. Of course, in every disease, all modifying influences must be taken into consideration. Your age, your calm, philosophical state of mind, are all in your favor. An hysterical woman would probably be dead in twelve months. I think it is possible that you may live for three years, but extremely improbable that you can last for four. Indeed, I am convinced that four years is a very wide margin to give you, I have spoken plainly, believing that your desire was for strict candor."

Gordon Paston listened attentively to every word, and Dr. Hendon could not but admire the unmoved countenance with which he received his death sentence.

There was a short pause, and then the victim spoke.

"Your verdict, doctor, is much what I expected, and I hope you will forgive me when I tell you that I think you are mistaken in your estimate. Whether it is that I have a peculiarly sanguine temperament, I know not, but, although five doctors at least have told me the same, most, indeed, giving me even a shorter tether, I feel it impossible to believe in so speedy a termination to my life. Were it not so, my course would be clear. I should year by year sell out a thousand pounds' worth of my investments, and spend that sum in addition to the income accruing from the remainder, but, incredulous as I am I feel that I dare not run the risk of finding myself pennyless if I should survive my appointed time. Now, I have a proposal to make to you, doctor, somewhat of a sporting nature. I want to ask you to back your opinion against mine. I hope you will not think me impertinent, but it would ease my mind greatly if you would fall in with my suggestion."

He paused a moment, but Dr. Hendon motioned him to proceed, half guessing in his mind what the proposal was to be.

"Now, you say, doctor, that I cannot by any possibility live more than four years and consequently that, spending £1,500 a year, I shall not at most run through more than three-fourths of my capital. Are you then prepared, for the sum of £8,000 down, to guarantee to pay me £1,500 a year for the rest of my natural life? According to your estimate you are sure of clearing at least £2,000 and very possibly a good deal more; and, further, you will relieve me of a very great anxiety. Fifteen hundred pounds a year is ample for my wants. What do you say, doctor; is it a bargain?"

Gordon Paston little guessed as he spoke what a godsend this seemed to the doctor. With £8,000 down, not only could he satisfy all his creditors, but, what was more tempting, he would have available money in plenty to back his fancy for the Derby.

The long and short of it was that, after some discussion, a formal document was drawn up and signed, and £8,000 was handed over by Mr. Gordon Paston to Dr. Herbert Hendon in consideration of the latter undertaking to pay to the former for the rest of his natural life the sum of £1,500 per annum, to take effect from June 1, 1887.

As a further security, a guarantee was obtained from a complaisant brother of the doctor, who undertook to be answerable for the due performance of this undertaking in case he should fail to carry it out.

Dr. Hendon had proposed that the amount should be paid quarterly, but Gordon Paston had insisted upon the whole £1,500 being paid him down once a year, and that on June 1. So it was that the recurrence of that date came to be of considerable importance to both persons of our drama.

And the doctor backed his fancy heavily for the 1887 Derby; but, unfortunately for him, his money was not on Merry Hampton.

* * * * * * * * *

Nearly four years had passed, and the £8,000 had long ago found its way, in company with a very large proportion of his professional income, into the pockets of Dr. Hendon's creditors. During that period the passion for gambling that was in his blood had led him to speculate in the city, and, where before he had risked hundreds upon pigmies in pigskins, now he risked thousands in gold mines guiltless of gold, and in the stock of corporations which only had an existence, like the world of the transcendalist, in the brains of men.

Gordon Paston was now in the last stages of his disease, but there was little doubt that he would live over June 1, when another £1,500 would be due to him.

Between him and Dr. Hendon during these three years there had sprung up a very close and intimate friendship. Indeed, excepting the latter's financial difficulties, they hardly had an interest which they did not communicate. Gordon Paston was a man of exceptional culture, intensely sympathetic, and in touch with the intellectual and artistic movement of the times, though unable, on account of his failing strength, to associate actively, as he would have loved to do, with the men and women who were workers. Dr. Hendon, on the other hand, was essentially the man of action—a platform speaker, a diner-out, a man who made his presence felt on councils and committees. He was the true complement to his friend and patient, and the happiest hours of both were spent in each other's company.

Often and often during the past year, when his strength had been more rapidly failing, had Gordon Paston forced his friend to the discussion of the physical aspect of death, and more than once he had insisted that when the last pangs came on and all joy of living was inevitably passed, there might be a more unfriendly action than that of a gentle and painless acceleration.

It was in the last weeks of May, 1891, that Dr. Hendon found himself involved in the most hopeless financial difficulty. Tradesmen were growing clamorous. Bankruptcy proceedings were threatening him on all sides, and, to crown all, the £1,500, due on June 1 to his dying friend, had to be found.

More than once Gordon Paston, all unconscious as he was of Hendon's financial difficulties, had laughingly said to him that he would do him out of another year's income. Indeed, the last time they had met he had said:

"Mind, old fellow, you have your check written for the 1st," and Herbert Hendon had sworn that nothing should make him forget it.

And as he had left the house he had said to himself with a groan:

"Would to God I was in that dear man's place; but, thank God, he is not in mine! Hell can, indeed, begin this side the grave."

On the 25th of May, just a week before the fatal day, he was paying his daily visits.

Gordon Paston was now failing rapidly. Indeed, for the last two months it had been evident that the end was approaching. His sister, Mrs. Fairfax, was in constant attendance upon him.

"Hendon," he said, as soon as they were alone that evening, "I have a little matter of business I want to speak about to you. My sister, Mrs. Fairfax, has been most awfully good to me, and I should like much to give her a little pleasant surprise. Now you know, as I told you four years ago, I felt justified, because of her husband's wealth, in not having any money available at my death for legacies. But, as a matter of fact, one of her boys is a godson of mine, and I think it would gratify her immensely if I presented her with the sum of £1,500, which will be due to me from you on the 1st of June, for the boy. Do you see?"

"I see," said the doctor, with a chill at his heart.

"And, old fellow," continued Gordon, "I want you to do me the favor of writing me your check now, post dating it, of course, for June 1st, this day week. I should like to have it by me, ready to put into her hand on the morning of that day."

"Oh, certainly," said Hendon, for he felt, in his apprehension, that any hesitancy on his part to comply might divulge his secret, and the last thing he could bear would be the forfeiture of the friendship and respect of Gordon Paston just now, when their parting must be so near.

So down he sat, with as much sang froid as he could muster, and wrote a draft for £1,500 on an account which could not boast one quarter of that amount. How it was to be swelled to that sum within the course of a week he had not the remotest idea.

On May 31st Dr. Hendon received an urgent summons from Mrs. Fairfax.

On his arrival at the house he was informed that his patient had passed a very restless night, and in the early morning had fallen into a state of unconsciousness. Dr. Hendon at once knew that the last stage of the disease had arrived, and that the prolongation of life was a mere question of hours. There might be a temporary return of consciousness, he said, but he could do little for him. Yes, if Mrs. Fairfax wished, he would call in again the last thing at night. All through that day Herbert Herndon was on tenterhooks—he knew that it was just touch and go whether Gordon Paston would live over the night. If he did, the draft for £1,500 would become due to him, his heirs, executors or assigns, and he, Herbert Hendon, would be a ruined man. The anxiety was cruel. A few labored and probably unconscious breathings more or less meant to him immediate ruin or temporary salvation.

By the time his 8 o'clock dinner was over, after which he had promised to call, Dr. Hendon had worked himself up into a high state of nervousness.

Mrs. Fairfax met him at the door.

"Yes, he is still breathing, poor fellow," she said, in answer to the doctor's inquiry, "but that is all one can say. At 5 o'clock he regained consciousness for about half an hour."

"Did he speak at all?"

"Yes, he asked me what day of the month it was, and, when I told him May 31, he said: 'Oh, I do hope I shall live till to-morrow. That'll be the 1st of June.' He said little else except that he had made a will which would be found sealed up in his desk. Almost the last words he said were: 'Hendon was right and I was wrong. I should like to thank Hendon for all his kindness to me.' He said nothing else besides giving a few tender and thoughtful messages for my husband and children, whom he feared he would never see again."

Whether this meant that mention had been made of the intended gift Hendon could not tell.

By this time they had reached the sick-chamber. The doctor saw at a glance that the end was very near.

At that moment a neighboring church clock struck the hour of ten.

The sick man stirred uneasily, and threw his arms about. Dr. Hendon took his wrist in his fingers and felt the pulse. It was scarcely perceptible. Yes; a little stimulant might fan the flickering flame into a few hours of life. Yet he hesitated. What were a few hours of unconscious life worth to him?

"I fear we can do nothing," he whispered to Mrs. Fairfax. "The end is close at hand."

"Stay with us till it is over, doctor."

Dr. Hendon bowed and sat down by the bedside.

There was a deep silence in the room, only the clock's tick-tack could be heard, and Dr. Hendon yearned toward the sick man who lay there in his helplessness, and whom he had learned to love so well. The devil whispered, "He told you not to keep him alive when it was only pain to breathe." And the doctor settled himself down to wait. But his conscience would not let him rest. The man in him got the better of the devil.

He rose.

"I think," he whispered to Mrs. Fairfax, "we might see what a little stimulant will do for him."

At 8 o'clock in the morning of June 1, Dr. Hendon walked home through the deserted streets. But an hour before he had received a last word of thanks, a last pressure of the hand, a last loving, trustful look from the fast-glazing eyes of his friend—and, as he walked alone, he thanked God that he had deserved that look of trust; that it was with an honest pressure of the hand that he had encouraged his friend across the shadowy valley. Guilty though he had been of almost criminal folly in monetary transactions, led away though he had allowed himself to be by the lust for gambling, liable though he was (as soon as legal formalities could be gone through) for £1,500 to Mrs. Fairfax's boy, he yet trod the pavements with a light-heartedness which he not felt for many a long day. He had at least proved himself a friend faithful unto death. There was at least a particle of self-respect left to him.

* * * * * * * * * *

A week later he attended his late patient's funeral, and was invited to be present at the reading of his will. The only part which in any way concerned him was as follows:

"I give and bequeath to my dear friend and medical adviser, Herbert Hendon, the moiety of the sum of £20,000, due to me in reversion at the death of my great-aunt, Priscilla Paston, in consideration of his faithful care of me since May, 1887, and the disinterested manner in which he has prolonged a life, in more ways than one, a burden and oppression to him. Sanguine as I am that my life will by his skill be prolonged considerably over four years from that date, I will that this bequest shall not take effect in case of my death occurring before the first day of June, 1891."

BENEFICIAL HABITS.

THE SECRETS OF BEING HEALTHY, WEALTHY AND WISE.

A very thin young lady, of about thirty years, with a promising beau, came to consult about her "skin and bones." I had frequently met her when she seemed even more emaciated, but now she "would give the world to be plump." Sitting down in front of me, she began with, "Don't you think, doctor, that I look old for twenty?" I admitted that she looked rather old for twenty. "Can anything be done for me? What can I take for it? I should be willing to take a hundred bottles of the worst stuff in the world, if I could only get some fat on these bones. A friend of mine (her beau) was saying yesterday that he would give a fortune to see me round and plump." "Would you be willing to go to the Cliff Spring in Arkansas?" "I would start to-morrow." "But the waters are very bad to drink," I said. "I don't care how bad they are; I know I can drink them." "I asked you whether you were willing to go to the Arkansas Springs to test the strength of your purpose. It is not necessary to leave your home. Nine thin people in ten can become reasonably fat without such a sacrifice." "Why, doctor, I am delighted to hear it, but I suppose it is a lot of some awful bitter stuff." "Yes, it is a pretty bitter dose, and has to be taken every night." "I don't care; I would take it if it was ten times as bad. What is it? What is the name of it?" "The technical name of the stuff is 'Bedibus Nine-o'clockibus.'" "Why, doctor, what an awful name! I am sure I shall never be able to speak it. Is there no common English word to it?" "O yes. The English of it is, 'You must be in bed every night at nine o'clock.' We doctors generally use Latin. 'Bedibus Nine-o'clockibus' is the Latin for 'You must be in bed every night by nine o'clock.'" "O, that is dreadful. I thought it was something I could take." "It is. You must take your bed every night before the clock strikes nine." "No; but what I thought was that you would give me something in a bottle to take." "Of course, I know very well what you thought. That's the way with you, all of you. One person eats enormously of rich food till his stomach and liver refuse to budge; then he cries out, 'O, doctor, what can I take? I must take something.' Another fills his system with tobacco until his nerves are ruined; and then, trembling and full of horrors, he exclaims, 'O, doctor, what shall I take?' I write a prescription for him—Quitibus Chawibus et Smokibus." I will suppose my patient is not a classical scholar, as I am sure my reader is, and so I translate it for him into English. He cries out at once, "O, doctor, I thought you would give me something to take." Another sits up till thirteen or fourteen o'clock, leads a life of theatres and other dissipations, becomes pale, dyspeptic and wretched, and then flies to the doctor and cries out, "O, doctor, what shall I take? what shall I take?" "Now, madam, you are distressed because your lover has been looking at your 'skin and bones.'" "But, doctor, you are entirely"—"O, well, we'll say nothing about him, then. But tell me what time do you go to bed?" "As a general rule, about twelve o'clock." "Yes, I thought so. Now, if you will go to bed every night for six months at nine o'clock, without making any other change in your habits, you will gain ten pounds in weight and look five years younger. Your skin will become fresh, and your spirits improve wonderfully." "I'll do it. Though, of course, when I have company, or during the opera, I can't do it." "It is regularity that does the business. To sit up till twelve o'clock three nights of the week, and then get to bed at nine o'clock four nights, one might think would do very well, and that at any rate 'so far so good.' I don't think this every other night early, and every other night late, is much better than every night late. It is regularity that is vital in the case. Even sitting up one night a week deranges the nervous system for a whole week. I have sometimes thought that those people who sit up to eleven or twelve o'clock every night get on quite as well as those who turn in early six nights, and then sit up once a week till midnight. Regularity in sleep is every whit as important as regularity in food. At length my patient exclaimed, "Doctor, I will go to bed every night for six months before nine o'clock if it kills me, or rather if it breaks the hearts of all my friends." She did it. Twenty-one pounds was the gain in five months. Her spirits were happily enlivened, and she spent half her time in telling her friends of her delight with her new habits. She had no further cause to complain of skin and bones, and she had the special gratification of appearing more attractive in the eyes of her lover. He, like a sensible man, when he saw the good effects of the nine-o'clock-to-bed arrangement, heartily approved of it, and became a convert himself.—*Dio Lewis.*

THE WORLD'S TEMPERATURE.

THE COLDEST AND WARMEST REGIONS OF THE EARTH.

The knowledge of the extreme temperature conditions of our earth is not only of especial interest in physical geography, but also of general interest. I have, consequently, undertaken a comparison of the two regions which are especially distinguished, the one by its icy cold, the other by its oppressive heat. At the same time it may be remarked that man has a great power of adaptation to extreme climatic conditions, without prejudice to the persistence of the organism. The mean lowest temperature that has been recorded is for inner East Siberia, whose climatic conditions are very high atmospheric pressure in winter, with calm air and a clear bright sky, conditions which favor radiation and result in the development of a high degree of cold. The lowest temperature is in the Yakutsk region, especially in the departments of the Lena and the Jana. Here the thermometer during the winter months—December, January and February—indicates a mean temperature ranging from 12 deg. Fahr. below zero at Pitlekaj, to 55 deg. below zero at Werchojansk—which latter, as far as our knowledge extends, is the site of the greatest winter cold on earth. The town of Werchojansk is situated in the valley of the Jana, about one kilometer from the river's bank. The river is enclosed by mountain chains, in the middle of which the town is situated. The position of the valley is favorable to long-continued calms, and the ground being nearly always covered with snow, the conditions involve a sinking of the temperature to so very low a level that the icy cold gives way for a few months in the year only to the intense rays of the summer's sun. In January the temperature ranges from 24 deg. to 80 deg. below zero, and in July from 40 deg. to 86 deg. Fahr. To enable one to form an idea of the extreme cold to which Eastern Siberia owes its evil reputation, it is only necessary to bear in mind that in the coldest winters in Germany the greatest extremes of cold are rarely below zero. In the American Polar region the extremes of cold have been registered at about 75 deg. below zero, but in Werchojansk, the minima throughout December and January are invariably below that point. In the Southern Polar region the extremes of cold cannot be compared with those in Siberia and North America. "It is not possible," says Middendorff, in writing of the climate of Siberia, "to describe the awful dismalness of the region under the dominance of such fearful cold. One must experience it to form a conception of it. The quicksilver is long solidified, and can be cut and hammered like lead. Iron becomes brittle, and axes are shivered like glass. Wood, according to the measure of moisture frozen in it, is harder than iron, and absolutely resists the axe unless thoroughly dry. The flames which elsewhere leap up from the hearth, here clasp the burning wood closely, as if the fire itself were freezing. Indeed, if a draft should for a moment urge the flames higher, they are at once extinguished, so cold is the oxygen which supports combustion. The crackling of the brittle snow under the footfall is heard at a long distance. The trees of the forest burst with loud cracks, which are answered by subterraneous bursts of thunder resembling the cannonading of a distant battery, due to the bursting of the icy covering of the earth, and of the hard frozen soil. It seems incredible that animal and plant life can flourish under these conditions but such is the fact." Let us now institute a comparison between this land of eternal ice and the hottest region of the earth. This will be sought naturally in the Tropics on either side of the Equator. In this region in which the sun at noontide strikes down its vertical rays, it might be inferred that the difference of temperature between day and night would be very considerable. This is really not the case, partly because the Tropic Zone is three-fourths water which sensibly reduces the temperature, and partly because of the rich vegetation which covers the land in the tropics. The humidity of the atmosphere in the tropics is remarkable, and this exerts a powerful influence on organic life. A temperature of 97 deg. Fahr. is very rare in the tropics, and this is occasionally exceeded even in our latitudes. But the effect upon man in the two cases is very different; a hot dry air can be borne without inconvenience, while if the air is moisture-laden the same temperature becomes almost unendurable. The characteristic climatic feature of the tropic region is a high and equable temperature with dense humidity of the atmosphere. A glance at an isothermal chart teaches us that the belt of highest temperature passes through Southeastern Asia, the interior of North Africa, Arizona, and the centre of Australia. If we consider the total sum of heat to which any one region is exposed in the course of the year without reference to extremes, the southern coast of the Red Sea is the region of hottest mean temperature as far as our observations extend. The mean temperature of Massowah ranges from 78 deg. to 79 deg. in January and February, to 95 deg. to 96 deg. in July and August, with a mean annual temperature of 86 deg, a daily variation of 10 deg to 12 deg., and a mean annual range of 14 deg. to 15 deg. These figures do not appear excessive, the highest mean temperature is occasionatly exceeded in other regions, but the continuous, nearly uniform, high temperature renders it almost unendurable for Europeans. Between Suakim and Massowah the temperature of the sea at a depth of 1,241 metres was found to be 70 deg. According to Rohlfs the temperature of the well water at 4 to 5 metres deep is 93 deg. to 95 deg. The atmosphere is moderately moist and the clouds rare. Only in the rainy season, in the first months of the year, is the moisture appreciably greater and clouds plentiful. The evaporation is considerable. Nothing can compare with the feeling of exhaustion which overpowers the European in these tropic lands and seas. The passengers by the Indian steamers come from their baths to the dinner table, their clean clothes already saturated with perspiration; and after dinner lie about the deck panting for fresh air, and sighing in vain for rest and relief in sleep.

DR. W. J. VAN BEBBER.

DOMESTIC DIETETICS.

SPECIALLY PREPARED, FROM PRACTICAL TESTS, FOR THE LADY READERS OF THE "AMERICAN ANALYST."

SEASONABLE FOOD.

September.

GAME AND POULTRY.—Pigeon, chicken, duck, woodcock.

MEATS.—Beef, mutton, lamb, veal, ham, kidneys, liver, venison.

FRUITS.—Apples, bananas, blackberries, gooseberries, huckleberries, grapes, melons, oranges, peaches, pears, pineapple, plums, raspberries, currants.

FISH.—Bass, blackfish, bluefish, clams, cod, crabs, eels, flounders, halibut, herrings, lobster, mackerel, mussels, porgie, prawn, rockfish, salmon, trout, sea bass, sturgeon, turtle, white fish, whiting.

VEGETABLES.—Beets, beans, cabbage, carrots, cauliflower, corn, cucumbers, egg-plant, garlic, lettuce, onions, parsley, parsnips, potatoes, radishes, rhubarb, savoy, shallots, spinach, squash, tomatoes, turnips.

PRACTICAL RECIPES.

AMBER SOUP.—Fry with some bits of ham or bacon half a cup each of onion, carrot, turnip and parsnip. When they are a delicate brown turn contents of the pan in which they are into a soup pot and add a sprig of thyme and parsley, a bit of bay leaf, three cloves, and half a dozen whole peppers and cover with five quarts of stock. Simmer for an hour, then strain and clarify. Heat up again, season, add a tablespoonful of caramel and serve. If you have no stock on hand make a plain meat broth and proceed with the vegetables as above.

ONIONS IN BROWN GRAVY.—Peel and boil some small sweet onions and when tender pour off most of the water in which they were boiled and add some soup stock or beef gravy. After the onions have stewed in this for ten minutes take them out and keep them hot while you thicken the gravy with some browned flour. Boil up well, return the gravy and dish.

BROWNED PARSNIPS.—Mash two cups hot boiled parsnips and add to them butter, salt, pepper, and two large tablespoonfuls of cream or milk. Stir together until it boils, then put it in a buttered dish, cover with fine bread crumbs and dots of butter and brown in the oven.

ANCHOVY SALAD.—Take eight salted anchovies and wash, skin and bone them, then lay them in cold water and let them soak for an hour, then drain and dry them. Slice a couple of hard boiled eggs. Put the centre leaves of a fine head of lettuce in a salad dish, arrange the eggs and anchovies amongst it, pour a plain dressing over it and serve.

PLAIN DRESSING.—Three tablespoonfuls of olive oil, one tablespoonful of vinegar, the yolk of a hard boiled egg, pepper and salt. Mash the yolk with the salt and pepper, add the oil gradually, then the vinegar.

CHEESE RAMAKINS.—Grate half a pound of American cheese and half a pound of bread crumbs; soak the crumbs in half a pint of milk; put these in a mortar, add four ounces of sweet butter, half a saltspoon of white pepper, two saltspoons of salt and half a teaspoon of dry mustard; put the mixture in a bowl and add the beaten yolks of five eggs. Beat the whites to a stiff froth and add to the mixture. Heat and butter the gem pan, put in the mixture and bake twenty minutes. The mixture may be made stiff with flour, rolled into little cakes and baked on buttered paper.

BROILED SAUSAGES.—Split them in two lengthwise; place them between a double wire broiler and broil on the flat sides first, then turn and broil on the other; arrange a mound of hot apple sauce in the centre of a hot, flat dish, arrange the sausages upon it and serve.

COOKING EDUCATION.

A NEW SCHOOL OF COOKERY IN PARIS.

The following account of a new educational establishment for the training of chefs is furnished by the Paris correspondent of the London *Caterer*: "England has its National Training School of Cookery—why should not the classic land of *la cuisine* have a similar institution? One would have thought that in France such a school should have been founded years ago, whereas in reality Paris is one of the last cities to wake up to the importance of such an establishment. The fact is the French so long have considered themselves as the only born cooks in the world that they never thought it necessary to open an institution for learning this important art. Certainly, cooking is one of the glories of France, and when other nations wish to eat well they begin—as soon as their means permit—by engaging a French cook. However, it is a mistake to suppose that all French cooks are chefs, or that the mistress of every family understands the art of preparing nutritious food. The *maitres queux* themselves are of the opinion that French culinary art is declining, and that the population is dwindling away from anæmia and dyspepsia. Naturally, they do not ascribe this decline so much to their own shortcomings as to

the faults of their masters, and, above all, of their mistresses. Formerly, they say, the middle-class housewives, and even aristocratic ladies, did not blush at coming in contact with their cooks. To-day the mistress of the house takes very little interest in the practical details of the kitchen. Ladies consider that they have accomplished their duty in giving brief orders in the morning, and casting their eyes over the book of expenditures. This rapid examination, which is usually accompanied by severe criticism, discourages the cook in taking more than passing interest in his work. We are far from the period of Talleyrand, who declared that his chef, Gareme, had a large share in regulating the destinies of Europe. The old diplomatist never received guests at his table without first making a tour of the pantry, and casting his eye over the preparations for the repast. This is a historical fact. So much for the decline of good cooking in private houses. As for the degeneracy of the table in restaurants, it may be ascribed to the hurried mode of life of the present day. The gourmets are rare who have individual fancies or requirements that stimulate a chef to supreme efforts. Nowadays men rush into a restaurant, give their orders hurriedly, and wish to be served with all possible speed. Besides, there are a great many so-called chefs in private houses and restaurants who have never served any apprenticeship, whose cooking not only casts discredit upon the profession, but becomes a danger to the public health. A great many of these *gate-sauces* have little idea of scientific cooking, and seem to think that when they have prepared a showy dish they have made a wholesome one. This idea has prevailed so long among a number of would-be chefs that Anglo-Saxons in general share the opinion of the hearty Yorkshireman who had been spending some time in France, whose first exclamation upon landing in England was, "Give me a rump steak and a glass of beer; for the last 12 months I have been dining on ornaments." To react against this deplorable state of things in a country where the culinary art has held the lead for two centuries, the principal members of the French Cooks' Society decided some time ago to establish a professional school of cookery and alimentary science. The idea of the founders is to pursue a double end—to educate chefs who will maintain the renown of French cooking, and to show to middle-class and poorer housewives how they can prepare nutritious food by a moderate outlay. The work that these men have undertaken is a disinterested one. All the professors give, not only their time, but pecuniary aid, according to their means. The school is installed in a building by the side of the Ecole des Beaux-Arts. The building was formerly used by the Mont de Piete, and opens on a large courtyard, the entrance to which is in the Rue Bonaparte. On the ground floor is a dining room, a hall for lectures capable of accommodating 200 persons, opening on to a spacious kitchen, which is separated from the hall by a large table arranged with gas cooking stoves. Behind this table, and in the middle of the kitchen, is a superb cooking range, with all the latest improvements, while around are kitchen utensils in abundance. At one side of the kitchen, opposite the dining room, is a pastry cook's room, and another for cold dishes. Up-stairs there is a library of books and publications relating to the culinary art. The professional classes are held in the evening, and are destined to complete the practical education of apprentices who intend to become chefs, and are employed in private houses, restaurants, or other establishments where they obtain the rudiments of their profession. At the school they will pursue their education from a theoretical point of view, studying the history of their calling and of the dishes they prepare elsewhere, as well as the new inventions or improvements made by their teachers; they will extend their general knowledge of all that concerns their profession, and at the same time be able to perfect themselves in any special branch, according to their tastes or aptitudes. In the preparatory classes are taught the first principles of pastry making and cooking, the rules for preparing food, the elements of domestic economy, hygiene, household accounts, use and care of stoves and utensils, and the rudiments of history, geography, botany, etc., so far as they relate to the culinary art. As no French institution could exist without honorific distinctions, the graduates of this preparatory class will, upon the completion of their studies, receive a certificate of capacity which will enable them to follow a higher course. This upper course comprises a study of cooking, pastry making, preserves, liquors, charcuterie, and, in general, everything relating to the alimentary sciences, animal anatomy, carving, ornamentation of dishes, moulding, the care of the pantry, the wine cellar, table service, and the rest. Pupils having obtained certificates of capacity in the different branches can compete for a grand medal, which the founders of the school hope will serve the winners as a title for obtaining employment, not only as chefs in large public or private establishments, but as professors of the culinary art in schools or colleges. All pupils must be of French nationality, but foreign auditeurs or listeners are admitted to these courses, without, however, having a right to pass examination or receive diplomas. The financial resources of the school consist of subsidies given by the State and the City of Paris, the profits of the yearly culinary exhibitions of the French Cooks' Society, the subscriptions of the active and honorary members of the school, and the tuition fees paid by the pupils. The pupils of the preparatory class pay 20f. a year, and those of the higher class 50f. Where this training school is likely to accomplish excellent results is in its public lectures destined for young ladies, housewives and women cooks, which are given three afternoons a week. The lectures, delivered by competent chefs, are not intended to crowd the brain with notions of high feasting, but to teach the principles of average cooking, so that housewives will be able to prepare plain dishes. Thus far housewives have been obliged to a large extent to depend for information upon badly edited cookery books. These public lectures already are well attended. It is a curious sight to see the interest with which ladies following the practical demonstration of the professor preparing the dishes; they ask questions, take notes, listen attentively, look with all their eyes, inhale the culinary aromas, and, at the end of the lecture, taste the dishes that the professor has made in their presence. The school, as I have stated, has been founded under the auspices of the French Cooks' Society, an organization whose culinary exhibitions are celebrated among gourmets. This association counts among its members most of the recognized chefs, and the majority of these men are not only experts in the refinements of their art, but exceedingly intelligent. Many of them are contributors to *L'Art Culinaire*, the organ of the French cooks, edited by Maurice Dancourt, one of the active promoters of the school; and in this review they publish not only excellent recipes, but discuss learnedly questions pertaining to the table. In their turn all the *maitres queux* will give the benefit of their experience to the pupils of the school. At present the principal workers are our valued contributor, M. Alfred Suzanne, Messrs. Capdeville, Garlin, Driessens, Poulain and Morin, who deliver the day lectures and preside over the evening classes. These men are the founders of the school, for without their active perseverance the scheme would not have been brought to a successful conclusion. M. Suzanne was for many years the chef of the Earl of Wilton, and afterwards spent five years as the head of the Duke of Bedford's kitchen. His long residence in England has made him an authority on all English courses, which he now proposes to teach to his countrymen, together with special French dishes. M. Suzanne has written several works on the culinary art—among others, "One Hundred and Fifty Ways of Cooking Eggs" (the English rights of which are vested in the proprietors of the *Caterer*), and "One Hundred Methods of Preparing Potatoes," which is eighty more than the celebrated Parmentier himself knew. A passing mention is due to M. Louis Berenger, the president of the French Cooks' Society. M. Berenger was for three years the head cook of the Emperor of Russia. Although he now spends more time in improving his racing stud (which includes several Kentucky trotters) than in inventing new dishes, he still takes an interest in his old profession, and particularly in the success of this school, which he has been largely instrumental in forming.

BILE AND BILIOUSNESS.

Of all the organs of the human body, none is more unjustly treated or regarded than the liver. According to popular speech, if a person is out of sorts, it is a bilious headache; if his skin turns yellow or sallow, he is bilious; if he has gastritis or enteritis, his liver is out of order; if he has "that tired feeling," his liver needs touching up. In warm climates this sort of things becomes a shibboleth. It is not the liver that is primarily at fault; it is violating the simple and beautiful laws of nature, when the constitution is slowly undermined and disease inevitably appears. Often, indeed, does it make its appearance in the liver or about the function of that organ. Illustrations of this will suggest themselves to every reader. The society-woman who corsets herself until the liver and neighboring organs are compressed, irritated and inflamed. The habitual diner-out who loads his digestive system day after day and year after year with a frightful excess of rich and heavily-spiced and seasoned food. The convivial gentleman who consumes three or four bottles of fine wines or champagne every twenty-four hours. The weakly book-keeper or poor student who devotes all his time to sedentary occupations and none to exercise, sunlight and fresh air. These are but a few instances. In every case, the man and not his liver is to blame. In every case the good liver, besides doing its work properly and promptly warns and warns again his owner by headache and discoloration of the whites of the eyes or the complexion that he is leading a wrong course and that if he does not desist, disease will call him her own. It is hardly needful to describe the importance of the liver—how it acts in digestion and how it aids in purifying the blood. But it cannot be too often repeated that nothing which goes into the system will affect the liver directly or immediately. What is to be done then when the liver gives warning that something is wrong? Stop and obey the summons! Prompt compliance with nature's suggestions will save unknown pain and suffering and it may be life itself. In all these cases keep the pores and glands open and active by warm baths and hard rubbing with a towel. Turkish and Russian baths and massage are invaluable to those who enjoy those superb accessories of the toilet. Use a light diet with all the fruits and sub-acid vegetables you can. There is natural virtue in the tomato, summer squash, green pea, string bean, green corn, onion, asparagus and mushroom. Take plenty of light exercise and avail yourself of the sunshine and the open air the most you can. Then, above all, strengthen the vital functions and especially the liver with a regular course of Ayer's Sarsaparilla. It acts promptly but gradually. You can see the improvement from day to day, but as it simply aids Nature and follows in her footsteps, it effects no sudden revolution. Ayer's Sarsaparilla is merely a scientific combination of vegetable elements, which dispels humors from the system, increases vitality and stimulates the great internal organs. Taken regularly, the headaches cease, the bad complexion and the discolored eyes disappear, "the tired feeling" vanishes, and the rare enjoyment which attends perfect health comes back to the user.

Subscriptions $1 per year. Now is the time to subscribe.

BUSINESS NOTES.

HORSFORD'S ACID PHOSPHATE

Imparts new energy to the brain, giving the feeling and sense of increased intellectual power. Dr. A. M. Bilby, Mitchell, Dak., says: "I have used it in a number of cases of nervous debility, with very good results."

NEW PROCESS WITH IRON.—Dr. Emmens has perfected a new process for making wrought iron from pig metal without being subject to puddling. It is made by placing a number of thin sheet-iron plates and pig-iron in a vat of a chemical solution. These metals are then connected with a dynamo. The current is passed through the vat and causes the pure iron to be effectually separated from the impurities of the pig-iron and deposited on the sheet-iron plates. An idea of its durability is shown when a horse-shoe nail made from it, placed head down in a vise, can be twisted into an almost perfect screw without breaking. It is claimed that this wrought iron can in a cold state be twisted, without breaking, into any conceivable shape, and is said to be far superior to the finest Swedish metal.

ORIGINAL. No. 27.

Pompton Puffs.

BY MARION HARLAND.

3 cups of flour, 1 tablespoonful of butter, ½ teaspoonful of salt, 2 cups of milk, 4 eggs whites and yolks beaten separately, 1 heaping teaspoonful of Cleveland's baking powder.

Sift flour, baking powder and salt together twice, chop in the butter. Stir the beaten yolks into the milk and add the flour, then the frothed whites. Whip high and light and bake in cups in a quick oven.

Use only Cleveland's baking powder, the proportions are made for that.

Hot biscuit made with Cleveland's baking powder may be enjoyed even by those of weak digestion. Cleveland's is the anti-dyspeptic leavening agent. The leaven comes from cream of tartar and soda, nothing else; no ammonia or alum.

Short and sweet

—your hours of labor when you use *Pearline*. Without *Pearline, you may* work hard and do much; with *Pearline you will* work less and do more.

Pearline saves your clothes in the wash, and your temper in the washing. It is the continual rub, rub, rubbing, over a washboard in the old way with soap, that wears your clothes and makes hard work.

Pearline is the new way, and does away with the rubbing. It is as safe as it is sure; be sure to get *Pearline*—nothing else, and you will be safe.

Beware Peddlers and some unscrupulous grocers will tell you "this is as good as" or "the same as Pearline." IT'S FALSE—Pearline is never peddled, and if your grocer sends you something in place of Pearline, do the honest thing—*send it back*. 242 JAMES PYLE, New York.

PULP BOBBINS.—A bobbin made from wood pulp has been invented by a resident of New England. Some of its more important advantages over other bobbins are that it does not split or wear rough, which in present makes causes the yarn to be sometimes caught and broken.

RED COTTON.—Cotton of a red color is being grown in Georgia, where on an acre the cotton plants have stalks, leaves and flowers, every one of which is a deep red color. This crop is the product of a seed taken three years ago from two stalks of red cotton found in a cotton field. Attempts are being made to perpetuate this variety.

ADVERTISING GENIUS.—The writer of advertising matter must first be a business man with natural trade instincts, and have that analytical ability and keen perception which enables him to seize upon the appropriate and strong points of a business and present them to others in a winning and convincing manner.—*Profitable Advertising.*

ARTIFICIAL ALMONDS.—"Dutch Almonds," so called, are said, on the authority of the *British and Colonial Druggist*, to be very deceptive imitations of the genuine, though they are not almonds at all. They have much the appearance and flavor of the much prized nut; but their chief constituents are glucose and essence of mirbane. The inventors and makers of these artificial almonds carry on their business in Holland, and they are finding customers among confectioners in all parts of Europe. It will not be long before they will attack the American market, if, indeed this is not already the case.

DERIVATION OF CAUCUS.—As the rise and fall of the nations of antiquity may be traced by the study of comparative philology, so the history of any art or industry is reflected in that science, and the number of words which are contributed by a given profession may, to a certain extent, be taken as a measure of its importance. Thus the most influential guild of colonial times was the ship calkers of Boston. In those days a meeting of the calkers was usually held to decide upon political or other questions and was called a "calkers," hence our Latin-looking word "caucus."

SURVEY OF THE PACIFIC COAST.—After nineteen years the United States steamer Hassler has completed the survey of the California and Oregon coasts. The Hassler was built specially for this work in 1871, and on her maiden trip around Cape Horn, Professor Agassiz made a series of deep-sea dredgings along the coast of North and South America, with valuable results to science. The most interesting fact developed in the recent surveys is that the coast line of Southern California is more abrupt than that of any part of the Atlantic or other portion of the Pacific.—*Scientific American, July* 25.

ELECTRIC LAMP.—A peculiar kind of electric hand lamp for firemen is a recent English invention. The battery and lamp are contained in a copper case similar to a fireman's ordinary lamp, and fitted with a handle for convenience in carrying. Very powerful parabolic reflectors are provided, and the lamp, which has a duration of from two to three hours—after which it can easily be recharged—is said to form an important adjunct to the outfit of the fire brigade. The lamp is also suitable for use in mines, gas works, gunpowder and chemical factories. The advantages claimed for the device are portability, facility in charging, capability of resting the battery when the light is not required, and entire safety.

THE PIE CROP.—In the United States there are eaten every day 2,250 000 pies. Each week, 16,750,000. Each year, 819,000,000, at a total cost of $164,000,000—an amount greater than the internal revenue, and more than enough to pay the interest on the national debt. If the pies eaten every day were heaped one on top of another, they would make a tower thirty-seven miles high. If laid out in a line, they would reach from New York to Boston. With the yearly pie product of the United States a tower 13,468 miles high could be erected, and stretched in a line they would girdle the earth three times. These pies of a year would weigh 803,000 tons. And, if, as has been so often stated, figures don't lie, then certainly pie is a great institution.—*N. Y. Press.*

No. 42. **Beautiful 6-Room Cottage.** Handsomely designed; all modern improvements. Cost, $3,100.
No. 49. **Neat Village Church.** Seating capacity about 600. Cost, $7 500.
No. 50. **Store and Office Building.** Brick; 2 stores and 8 offices, very handsome. Cost, $7,000.
No. 51. **Modern Suburban Residence of Nine Rooms.** Beautiful design. Cost, $2,100.
No. 57. **Rosedale Cottage, 3 Rooms.** With Bay Window, Frame. Cost, $1,000.

TABASCO PEPPER SAUCE,

OR LIQUID PEPPER.

Is simply the Pulp of the Ripe Pepper Extracted by Pressure.

The seed of this Pepper was obtained from Central America, and by careful cultivation in Louisiana for many years has been so improved in strength, flavor and aroma, as to have become a new variety of Red Pepper, superior to all others. The pulp is so handled as to retain all the flavor, strength, aroma and color of the ripe fruit, and to keep unimpaired in any climate. It excites the appetite, promotes digestion, and is pronounced by connoisseurs to be the finest condiment in the world. For medicinal purposes it recommends itself by its purity, strength and diffusible form.

THE QUEEN'S PRIZE SCHOOL OF HISTORY.

About two years ago the publishers of THE CANADIAN QUEEN added what has proven to be a very popular and successful feature to their publication in establishing their Prize History School. It has offered competitive examinations in English, Canadian and American History, giving valuable rewards to those making the most correct answers. During this time there have been added the names of over forty thousand new subscribers to their books Rewards have been made by THE QUEEN which have cost them in cash over ten thousand dollars. THE QUEEN'S Prize School of History has received the sanction and support of the clergy, press, and, in fact, of the best people of the Dominion of Canada. The following, taken from a leading daily newspaper, expresses an opinion which is universal:

A HANDSOME PRIZE.

AN EVIDENCE OF WHAT A GENUINE MAGAZINE COMPETITION OFFERS.

"On Friday there arrived from Toronto, for Miss M. Hora, a handsome Shetland pony, harness and cart, being the first award in the Royal Quilt Competition of THE CANADIAN QUEEN magazine. It attests the genuine nature of the magazine's contests by its excellent condition and value. THE QUEEN has frequent competitions and has made innumerable awards, displaying a generosity quite surprising to those who have had experience of the limited field for Canadian journalistic enterprise. But THE QUEEN has been a success as a business venture from the start, and is growing in literary excellence steadily. It covers the field of fashion, as well as light reading; talks to the household, the young, and, indeed, all home classes. The competitions have been used to assist the introduction of the magazine, for where it is introduced it is quite certain to remain a monthly guest. The leading prizes have been made, as instance this latest to Kingston, while many smaller prizes have rewarded the moderately successful among competitors. THE CANADIAN QUEEN is truly royal in its ways."—*The (Kingston, Ont.) Daily British Whig*, June 27th, 1891.

QUESTIONS IN AMERICAN HISTORY.

1.—Give the names of the early navigators who it is claimed by historians first discovered America.
2.—From whom has America taken its name?
3.—What class and nationality first settled Virginia? New York? Massachusetts? Pennsylvania? Maryland?
4.—What action did the Continental Congress of 1774 take and what was the result of that action?
5.—What was the first battle fought in the War of the Revolution?
6.—What nation rendered the Americans great assistance in the War of the Revolution?
7.—Give the names of the committee appointed to draft the famous Declaration of Independence.
8.—What was the date of the signing of the United States Constitution?
9.—After becoming a nation and before the great Civil War, what were the principal conflicts which engaged the Americans?
10.—What was the direct cause of the Civil War? What Generals of the Northern Army have occupied executive positions under the Federal Government since the closing of the War? Who was Commander-in-Chief and who were the principal Generals of the Confederate Army during the struggle?
11.—How long did this War last and what is the computed loss of life?
12.—What can be said to day of the United States as a nation?

To the *First* gentleman sending the correct answers to the above questions in American History the publishers of THE QUEEN will present "**Majestic**" acknowledged the **Handsomest and Finest Riding Horse in Ontario.** ("Majestic" is sixteen hands high, thoroughbred, seven years old, and valued at $350.00.) To the *First* lady the publishers of THE QUEEN will present an elegant **Jacket of Genuine Alaska Seal** to be made according to the measurement supplied by the winner. To the *First* boy under sixteen years of age the publishers of THE QUEEN will present a **Little Giant Safety Bicycle** valued at $75.00. To the *First* girl under sixteen years of age the publishers of THE QUEEN will present an elegant **Music Box,** playing twenty tunes, finely finished and valued at $55.00.

To the gentleman from whom the *Last* correct answers are received before the close of this Competition, the publishers of THE QUEEN will present a **First Cabin Passage to Europe and Return** and **$200 in Gold** for expenses. This trip can be taken by the winner any time before October 1st, 1892. To the lady from whom the *Last* correct answers are received before the close of this Competition the publishers of THE QUEEN will present a **Pony, Cart and Harness.** To the boy under sixteen years of age from whom the *Last* correct answers are received before the close of this Competition the publishers of THE QUEEN will present a **Solid Gold Watch** containing one of the best American movements, and valued at $75.00. To the girl under sixteen years of age from whom the *Last* correct answers are received before the close of this Competition the publishers of THE QUEEN will present an elegant **Solid Gold Watch,** containing one of the best American movements, and valued at $65.00.

ADDITIONAL PRIZES IN ORDER OF MERIT: Silver Tea Services, Ladies' Gold Watches, Silk Dress Patterns, French Mantel Clocks, Portiere Curtains, Toilet Cases, Manicure Sets, and many other useful and valuable articles.

The object of the publishers in offering these liberal prizes is to introduce THE QUEEN Magazine into **new** homes. Answers must be mailed *on or before* November 10th, 1891, and must be accompanied by $1.00 for one year's subscription to THE CANADIAN QUEEN. Prizes awarded to subscribers residing in the United States will be shipped to them **free of duty.** The distribution of awards is in the hands of disinterested persons, and decisions will be based on the correctness of answers. Use your own language in wording the answers. No corrections can be made after your answers are mailed. THE QUEEN is a large, forty-eight page family magazine, especially interesting to ladies and children, and visits regularly **over one hundred thousand of the best homes** in Canada and the United States. The awards in THE QUEEN'S PRIZE SCHOOL OF HISTORY are made strictly with regard to merit, without partiality to persons or locality. The decisions must be accepted as final. If you have never seen a copy of THE QUEEN send six U. S. two cent stamps and receive a late number, post paid, containing letters from those who have received rewards in previous contests.

Address THE CANADIAN QUEEN, PRIZE SCHOOL OF HISTORY, 58 BAY STREET, TORONTO, CANADA.

To Subscribers, Readers and Advertisers.

SUBSCRIBERS' attention is called to the great variety of interesting and instructive subjects treated in this number. We respectfully ask the co-operation of our subscribers in extending our Subscription list, which will enable us still further to increase the value of the AMERICAN ANALYST to them.

The CASUAL READER is specially requested to examine our liberal premium offer.

ADVERTISERS who do not know of this Journal already, are respectfully referred to article headed "A Business Benefit."

ALL are kindly requested to peruse this number thoroughly.

The AMERICAN ANALYST can be had at any news stand in the United States. Any newsdealer will take orders for it, the American News Company being our wholesale agents. All postmasters will receive subscriptions.

VALUE OF FOOD ANALYSIS.

An editorial article in the *Journal of the American Medical Association* makes short work of the prevalent fashion of proving a food to be valuable because a chemical analysis has shown it to contain some of the valuable elements of a food. One of the first of the artificial foods for infants was that of Liebig. It was made by a master hand, so far at least as its chemistry was concerned. It contained the exact amounts of albumen, sugar, fat and salts necessary for the nutrition of the child; but an extensive use proved that it failed in its object. The lesson which it teaches is only slowly gaining ground. That lesson is that the animal organism requires something more for its maintenance than so much albumen, so much fat, and sugar, and mineral matter. It requires that these substances shall be of such kind, and in such form, that they can be both digested and assimilated. The examination of the food of the properly nourished individual shows that he requires, for instance, a given amount of proteid. Certain foods contain the proper amount of proteids. It is thereupon assumed that these foods will answer the requirements of nutrition, which does not always happen. This is not the first nor the only time that physicians have been misled by a name. It is a little difficult to realize that a name is only a convenient tag, and does not always reveal completely the contents of the bundle to which it is attached. What is a proteid? Something which has certain definite chemical reactions. Certain differences in reaction enable chemists to separate in a crude but convenient way the proteids into several classes. But the separation of the proteids into classes, and indeed the very recognition of the proteids themselves, is by no means wholly artificial, and the several tests for these purposes give no idea whatever of the structure of these substances. The various proteids certainly are available as food-stuffs, but under what conditions each is most effective as a nutrient is not known. Moreover, this question is a biological one, and, at present, at least, far beyond the ability of chemistry to answer. It should therefore be clearly realized that the term proteid is a purely chemical one, and gives name to a group of substances which answer the requirements of indirect, almost artificial, chemical tests, and that the taking of the word in the broader biological sense, and making practical application as such, is liable to terminate in disappointment, as in the Liebig instance. Physiologists have shown conclusively that common salt is the only mineral substance, iron possibly excepted, which has a direct food value. All other so-called mineral elements are available for food only when they form constituent parts of the complex molecules of the various organic food-stuffs. For instance, it has been attempted to supply the deficiency of lime in the bones in rickets by the administration of calcium phosphate, but without success. The animal organism is unable to build calcium phosphate into the bone tissue. It must receive its calcium and its phosphorus in some other combination. This combination, to be assimilable, must be an organic one, such as is found in the yolk of the egg, to give a single example. To destroy a cereal by heat, to obtain from the ash the phosphate produced, is an illogical procedure. Identically the same products can be formed in the laboratory at much cheaper rates. The condition which made this ash available as a food was its existence in organic combination in the grain, and this availability was destroyed with the destruction of the grain. A well-known member of the association once remarked that the chemical test of a beef extract, showing how much albumen it contained, was practically useless to the physician—that the only sure test of the value of a food was the clinical observation of its assimilability. It is not intended to deny that chemical analysis is of value in assisting in the selection of foods, but one must be guided in making these analyses by a clear and full idea of their scope and their limitations. Ultimate analyses of foods are of very little use in determining the nutritive value of these substances, and are often very misleading.

THE EARTH A DYNAMO.

Our readers will derive great satisfaction in the perusal of an article published elsewhere in this issue in reference to the magnetic influence of the sun. The paper as we present it is condensed from a communication in the *N. Y. Tribune* from "an occasional" Washington correspondent, and everybody, we think, will agree with that journal that it must be a dull mind which is not fascinated by Professor Bigelow's discovery that the earth is a cosmical dynamo, generating electricity within itself by revolving in front of a magnet more than ninety millions of miles away. What makes such strong appeals to human imagination as the enormous dimensions of heavenly bodies, the terrible velocities with which the planets and our whole solar system whirl through space, or the infinities of time and distance? And yet are these things any more wonderful than the minutiæ of structure which the microscope reveals? How amazing it is that a few hair-lines on the little rainbow obtained in a spectroscope should tell us unerringly the composition of stars almost incalculably far away! And to think that a bit of steel, hung on a pivot and provided with a tiny mirror to register its tremors, should be able to tell us about convulsions on the solar surface to which the Martinique cyclone is as the maiden's sigh to that grim hurricane! To the telescope, camera, spectroscope, polariscope and barometer, in analyzing those solar activities on which human welfare so largely depends, is now added, as never before, the magnetic needle. And this instrument, unlike its fellow-inquisitors, works continuously, hour after hour, day and night, rain or shine, besides making a permanent record of its own unobserved indications. The special value of Professor Bigelow's recent discoveries lies, not in the freshness of his main idea, but in his magnificent demonstration of its correctness. Lagrange, of the Brussels Observatory, and others have conceived that the sun might be a magnet, which induced magnetism in the earth; but no one until now has made that theory a safe foundation of further logical processes. A fresh mode of attacking several tempting but baffling problems is now offered; such as the precise period of the sun's rotation, the nature of the coronal envelope about the orb of day, the connection between this latter phenomenon and the varying frequency of sun-spots and the shifting positions of the spot-zones, and in turn, the apparent relation between all three of these, the aurora borealis and the curious variations of the compass. In proving that sunlight is really magnetic, and that it exerts its influence upon the earth in rays parallel to those of heat and light, Professor Bigelow has accomplished a unique and important work. His discoveries become the more credible, on the one hand, by reason of the recent revelations, by Maxwell and Hertz, of the intimate relations existing between electricity and light, and, on the other, strengthen the conclusion to which those investigators are leading scientists, that light is

hereafter to be studied as a magnetic phenomenon. It is also a commendation of his work that he connects and unifies, as no one else has been able to do, an immense variety of apparently inconsistent facts, and at a time when popular pride in all that is American is peculiarly keen.

TO PREVENT FROST.

Artificial frost prevention is now suggested as an outgrowth of Senator Farwell's scheme for artificial rain production. A gentleman of Chicago has written a letter to Secretary Rusk on the subject. His theory is that clouds of artificial mists prevent the radiation of the heat from the earth. He suggests that the machinery and materials used by Col. Dyrenfurth in causing rain be tested as a means for bringing the clouds closer to the earth and of creating a sort of fog, which will be a preventive against the ravages of frost. At this rate it will not be long before man will expect to adjust the atmosphere and the weather in any manner that suits him.

THE SUN A MAGNET.

SOME INTERESTING DISCOVERIES OF A WASHINGTON ASTRONOMER.

A stir has been created recently in scientific circles, by an announcement of Professor Frank H. Bigelow. For over a year he has been laboring to demonstrate, what has been suspected, but never before has been proven, that the sun is either a magnet or very much like one, in its influence on other heavenly bodies, and that the strange phenomena of terrestrial magnetism spring from that source. This work, which was original in method, and exceedingly intricate and difficult, has at last reached a stage which experts accept as success. This important discovery promises to unlock several hitherto impenetrable mysteries of the universe, to open new fields of research, and to win lasting and high renown both for this young scientist and his country. Professor Bigelow started out, more than two years ago, by attempting to explain the solar corona as of magnetic origin. This beautiful and marvellous spectacle is only to be seen when the sun itself is completely obscured by the moon in total eclipse. It stretches out from the edge of the disc like an irregular halo, in some places and at certain times extending a distance nearly equal to a solar diameter, the outline somewhat suggesting several wings, and altogether being roughly star-shaped. But it fluctuates in figure and extent greatly. A very generally held opinion as to its nature has been that it is gaseous, the spectroscope revealing therein hydrogen and various vaporized metals, besides some substances whose composition is not known. But as meteorites fall through it without much, if any, perceptible resistance, obviously the outer envelop of the sun is of a very delicate texture. Another feature of the corona is that it seems to radiate in fine streaks which are not entirely straight, but slightly curved. It is this curvature that is the foundation of Professor Bigelow's discovery. He conceived that the coronal streamers or rays might correspond to what Faraday called "the lines of force" in a spherical magnet, and set out to see if this were true. Every schoolboy and schoolgirl who has studied natural philosophy recalls the pictures of iron filings on a sheet of paper, grouped like feathery fringes about the ends of a horseshoe magnet placed below. These filaments tend to organize into radiant lines, leaving one pole of the magnet and entering the other. The precise direction and shape of these lines in a spherical magnet have been carefully studied and described by such eminent physicists as Maxwell, Mascart, Thomson and Tait, and whether the coronal lines corresponded to these, was to be ascertained by an elaborate mathematical method known as "analysis by spherical harmonics." The first test was made with a photograph of the corona taken on January 1, 1889, by the Harvard eclipse party. The harmony between the curve of the lines there exhibited, and that which theory prescribes was so close as to give substantial confirmation of Professor Bigelow's suspicion. This led to a paper on the subject, published by the Smithsonian Institution in October, 1889, and recommended for publication by Professors Cleveland Abbe and Asaph Hall. Professor Bigelow was associated with the astronomical work of the United States Scientific Expedition to West Africa in 1889–'90, but failed to get at Loando a photograph of the December (1889) eclipse; but upon his return to Washington a year ago last spring he secured pictures which others had taken of this and other coronas, and laboriously examined them to see if they too bore out his theory; which they did. His discussion of a photograph taken by Professor Asaph Hall at La Junta, Col., July 29, 1878, was published by *The American Journal of Science*, in November, 1890. In still another article on "The Solar Corona," in that same magazine for last July, he deals with a third coronal photograph, obtained on December 22, 1889, at Cayenne, South America, by Professor Schaeberle; and in this connection he gives illustrations of his models of the three globes with bent wires inserted to represent the coronal streamers. These rays are grouped about either pole in a zone about 10 degrees wide, the centre of the belt being about 34 degrees from the pole; and all in one hemisphere, curving so that if continued far enough they would enter the other hemisphere in the corresponding zone. The matter composing the coronal streamers is believed to be shot up from the sun by some expelling force, but it ceases to be incandescent and visible at a short distance. It is part of Professor Bigelow's theory that sun spots are caused, in part, if not wholly, by the falling of this matter perpendicularly to the sun's surface; and as it ascends from high latitudes in rocket-like curves which bend over toward the equator, this deposit would of course fall nearer to the equator the more powerful the original ejection. Therefore he connects, as cause and effect, the weaker coronal development observed at the minimum stage of the eleven-year cycle with the higher latitude in which spots are then found, and the greater coronal extension at the maximum period with the greater proximity of the spots to the equator. Some of the coronal matter, the lighter part, of course, may not be deposited on the sun, he thinks, but, being carried along the lines of force to the plane of the equator, it may become distributed out in space in that plane so as to cause that other mysterious appearance, "the zodiacal light." One use which Professor Bigelow has made of this discovery is to ascertain, in a way never before possible, how long certain parts of the sun were in making a complete revolution. A study of spots has shown that the regions near the equator revolve faster than those near the poles. But spots are seldom or never seen in either hemisphere in higher latitude than 45 degrees. Fortunately the centres about which the coronal belts are arranged, and which Professor Bigelow, for convenience, calls the sun's "coronal poles," are not identical with the geographical poles, but are about 4½ degress to one side. Hence they will be in different positions, as regards the axis of rotation, at different times. Having located them, then, in each of his three photographs, taken in different years, he is enabled to compute precisely the time required for a single revolution, which he finds to be 27 days, 9 hours, 52 minutes, 52 seconds. He can now easily locate the position of those poles at any future hour or minute. Professor Bigelow is very careful to avoid calling the sun a "magnet." He merely proves that it is a "polarized body," acting like one. He takes pains to say that the influence exhibited in the corona, whether it really be magnetism or some other cosmical force (or form of force), related to it much as light is to heat, it is simply subject to the same mathematical laws as magnetism. The same principle by which Newton explained the fall of the apple to the earth also shows why the planets stay in their regular orbits about the sun, instead of flying off into space. But attraction formed only part of that great philosopher's system. Repulsion is also included in it. And many of the mathematical formulæ applicable in discussing phenomena of the former class are also suited to the latter, with merely a change of algebraic signs from plus to minus. Great mathematical problems relating to electricity and magnetism are solved by this method or "function;" and Professor Bigelow merely claims that the polarization of the sun, and the solar control of terrestrial magnetism are instances of "the Newtonian Potential Function in the case of Repulsion." The problem of the aurora borealis is the next one which Professor Bigelow undertook. The intimate relation it bears to terrestrial magnetism is clearly shown by the agitation of the magnetic needles at times of great auroral displays, while in turn its relation to solar activity is proven by the greater abundance of "northern lights" at the maximum stage of sun spots in the eleven-year cycle. Yet the "how" and "why" of this lovely phenomenon are yet mysteries. In that the aurora occurs only in a comparatively narrow belt about the magnetic pole of the earth, it closely resembles the arrangement of a corona about the sun's poles. If, now, those vast, flickering, brilliant streamers which form such a conspicuous feature of our auroral displays could be shown to conform to the "lines of magnetic force" emerging from the earth, we should have a more complete demonstration of their nature and of the harmony between solar and terrestrial phenomena. We might also find, then, upon further examination, that not only did the sun act upon the earth through the medium of interstellar ether, by magnetic induction, but that the earth reacts upon the moon in a similar manner, that is, magnetically. But, as Professor Bigelow showed in the *American Journal of Science* for last February, and also in a recent talk before the astronomical section of the American Association for the Advancement of Science, the observations of aurora thus far have not been precise enough for him to make that comparison. He points out how measurements should be taken in order to be available, and appeals to observers to act on the hints he affords. Meantime he has built up the mathematical formulæ wherewith to handle the data when he gets it, and has designed an instrument, which has been made for him by the United States Coast and Geodetic Survey, to facilitate his test. But it is Professor Bigelow's recent discovery regarding terrestrial magnetism which is of the greatest immediate practical importance, to say nothing of its far-reaching results. It comes just at the moment when the scientific world was on the verge of abandoning an elaborate, concerted movement for solving a great mystery. "True as the needle to the pole," like many other similes, is an imperfect comparison. That little strip of steel, by which every navigator in the civilized globe steers his craft, and by which every acre of land in the world is surveyed before its bounds are designated for record, does not, except in rare instances, point due north, nor is it stationary. Its direction is toward a certain centre called a magnetic pole some distance from the geographical pole; and but for carefully drawn charts, making proper connections for the greater or less variation in every part of the globe, our ships would be wrecked and our boundaries would be wrong, through the false guidance of the compass. There is, moreover, a small daily oscillation. After remaining steady all night, the needle will at daybreak, in our hemisphere, begin to swing very slowly eastward until eight or nine or ten o'clock, and then move westward past the starting point until noon or 2 P. M., after which it returns, reaching its ordinary position by or before sunset. This oscillation is very small—practically nothing at the equator, about five to eight minutes of an arc at Washington and Philadelphia, rather more in Toronto, still

greater in Labrador, and up on Lady Franklin Bay, in north latitude 81.44, as much as two full degrees on some days. This oscillation—which, by the way, is quite distinct from the more sudden, violent and irregular perturbations called "magnetic storms"—is greater in summer than in winter, greater at the equinoxes than at the solstices, and from 50 to 75 per cent. greater at the maximum than at the minimum stage of sun-spot frequency in the eleven-year cycle. In the southern hemisphere the swing is in the reverse direction; and there are a few stations where there is a double instead of only a single complete daily fluctuation. To the discovery of these facts the world owes much to Sir Edward Sabine, who secured the establishment of magnetic observatories, under British auspices, at home and in the colonies; although not a little credit is due to Dr. A. D. Bache, of the United States Coast Survey, and to the scientists of other lands. In order further to investigate this matter, and largely with a hope of finding some uuderlying law that would explain the phenomena already mentioned, a series of co-operative observations were taken in 1882–83, under the auspices of several Governments, at thirteen circumpolar stations, eleven in the northern hemisphere and two in the southern. The data had all been printed and discussed without result, and until a few days ago it was expected that when the International Polar Conference met in Munich this month it would dissolve its organization and cease its efforts. But Gen. A. W. Greely, the American delegate, takes with him the announcement of Professor Bigelow's discovery, and will urge continued observation with special reference to the soundness of the theories involved, and extending their application. Professor Bigelow's explanation is accepted as correct by so learned a man as Professor Cleveland Abbe, who last year presided over the section of physics in the American Association for the Advancement of Science; by Dr. C. A. Schott, for forty years in charge of the magnetic work of the United States Coast and Geodetic Survey; by Professor Mark W. Harrington, the new chief of the Government Weather Bureau at Washington, himself an expert astronomer and mathematician, and by General Greely. It was received with much favor, after a short verbal exposition, by the astronomers at the recent meeting of the American Association for the Advancement of Science, and without doubt it will profoundly impress the European savants to whose notice it is about to be brought. Terrestrial magnetism results, Professor Bigelow believes, from solar energy transmitted to the earth along two sets of lines; one the coronal, curved, and crossing the plane of the ecliptic near us perpendicularly; the other, straight, like the rays of light and heat, and parallel with the ecliptic. The latter set he holds to be the most important, at least as regards the daily oscillation of the needle. What takes place every day, then, as the earth rotates in these rays is practically what takes place in a dynamo for producing electricity. It is only necessary to move any conducting substance past a magnet, across its "line of force," to have that conductor made a magnet itself for the time being by "induction," and for a system of electrical currents circulating around its axis to be excited. While the conductor approaches, its nearest end acquires, let us say, north-pole magnetism, and the surrounding currents go in one direction, counter-clock-wise; but when the moving conductor has passed the stationary magnet, this same nearest end, now receding, reverses its polarity, and is like a south pole. In a dynamo there are scores, not to say hundreds, of such conductors arranged on a circular, rotating frame, which are thus brought in succession toward and away from the dominating magnets. Professor Bigelow conceives of each spot on the earth's surface as being rotated daily past the sun, and going through this same experience. From dawn to noon it approaches; from noon to sunset it recedes. The various instruments in an observatory registering the various components of the magnetic situation induced immediately underneath them first swing in one direction and then in the other, and when they are carried out of sight of the sun at night come to a state of rest; provided, of course, that no exterior disturbance arises. Were the earth stationary, this radiant influence would be felt instantaneously, but owing to its rotation there is a lag of about twenty-three degrees of longitude, or about an hour and a half of time. Along these radiating lines light and heat pass outward from the sun; the magnetic force is shown to be directed inward. To prove, or rather to build up this law, Professor Bigelow adopted the following method: Thirteen stations well distributed about the globe, especially in the northern hemisphere, were carefully selected. Their magnetic reports for June, 1883, were examined. This was one of the months of the international polar observation, and the sun now shone constantly in the arctic regions. For each of the twenty-four hours, at each station, the mean of magnetic disturbance, in extent and direction, was computed. And then, with due regard for longitude, a distribution of figures was made which would show the exact magnetic situation at all points at a certain given instant. Of course, the instruments at each station were at a different stage of their diurnal swing from every other. This process was gone through with for twenty-four different hourly positions. This involved exceedingly intricate computations; which only advanced mathematicians can follow. But the result was a beautifully organized system of lines of force, corresponding to those which Maxwell and Thomson have already prescribed and illustrated, as to be found when a polarized sphere is inserted in a "field of force." Work in the immediate future, Professor Bigelow thinks, should be pushed in these directions: From the agreement between theory and observations certain "constants" should be ascertained. The strength of the solar magnetic field, the permeability of the earth, and the atmospheric resistance to magnetism. He would have the relations between magnetism and weather examined afresh from this new vantage ground; improved magnetic charts supplied to navigators; and observatories established, not as now, very much at random, but in picked localities, to render the record more perfect. He also believes that inequalities in the motion of the perihelion of Mercury and the moon's node—the one inadequately explained on the theory of an intra-Mercurial planet, and the other not accounted for by gravitation—can be cleared up by a proper use of his recent discovery.

TALKING OF THE FUTURE.

SOME SUGGESTIONS OF THE PHONOGRAPH'S POTENTIALITIES.

We repeatedly hear querulous inquiries as to what possible practical use the phonograph can ever be applied to—as though the gift of speech did not alone carry with it every imaginable possibility. But the astounding suggestiveness of the wonderful instrument is more directly hinted at in the subjoined communication of "The Prophet" to the *Electrical Review* than has been done by any other authority that has come to our notice. And it is evident that these suggestions are only a few that have first presented themselves to that brilliant writer's fertile imagination:

"In many ways has electricity affected language, and in many other ways will it continue to do so. The ten word restriction of the telegraph, and the five minute limit of the long distance telephone have imparted a telegraphic brevity to our style which is not altogether to be deplored, especially as it quickens the revolt against the long-winded two-volume novel in favor of the short story, which is constructed with some reference to the amount of time at our disposal during this life here upon earth. In speaking of the short story, no less an authority than Edgar Allan Poe says that it is that class of composition which should best fulfil the demands of high genius. The future of letters and style will be greatly influenced by the phonograph. In fact, by it have those very words themselves been restored to the original meanings which they had in the time of Pliny. How appropriate it is to call the wax record of the phonograph a letter, for that word is from the Latin *linere*, *litum*, to besmear or rub over as with wax; and one of the first means of writing adopted by primitive man was by graving upon wax-covered tablets with a stylus (hence our word style), which was a sharp pointed instrument, made originally of metal, but after a Roman school-master was killed by one in the hands of a pupil, horn was substituted. Although destined to play a most important part as an educational adjunct, the phonograph as yet has no place in the school-room; but if introduced in its present form it would make the death of the Roman school-master seem euthanasia compared with the fate of the modern pedagogue at the hands of the small boy. The general exchange of phonographic letters throughout the different parts of our country, which is sure to come in time, will have a bracing effect upon the art of elocution, which seems to have been forced into a secondary position by the great magazine and daily newspaper of the present age. One of the developments which may be confidently expected is the phonographic dictionary, which shall be so constructed that the busy correspondent, by simply touching a button, may have any word properly spelled, pronounced and defined, with the usual etymological data appended, all given in the most approved tones of the elocutionist's art. Indeed, a phonograph in the elevated trains, announcing the stations in the clear, penetrating voice of Senator Ingalls, would be a pleasant relief from the fad for the Slavic languages in which the guards have indulged for so long a period. The horological phonograph, which will announce the various hours of the day, with a few remarks appropriate to the time, has not yet made its appearance among us, but will come with the perfected machine. When it does come, it will no longer be necessary to get up in the cold at night to strike a light in order to find out the time, for, by remaining in bed and simply touching a button, the hour, minute, and even second will be announced to you with all the politeness of a trained servant. In the art of music the phonograph will work its greatest change. Let the makers of music and musical instruments study this instrument and study it well. Its greatest wonder is yet to be told."

POWERFUL PRESSES.—The first large forging press that ever was made is now in full work at the armor plate manufactory (in Sheffield) of John Brown & Co. It is described as of 4,000 tons, and is worked by 2,000 horse-power pumping engines, and commanded by powerful travelling cranes capable of lifting 150 tons. At the works of Krupp, also those of Schneider & Co. in France, similar processes are now at work, and one has been erected at the Terni works in Italy, where the forging of guns and armor plates is largely carried on. A 4,000-ton press has also been made for a Chatillon company.

STEAM AND GAS.—A new method of working motor engines with hot gases and steam is now creating no little interest in English circles. According to this plan the mixture of the steam with the hot gases, to form a charge for doing duty in the working cylinder of the engine, is effected in the following way: First, the chamber having supplied a charge of mixture to the working cylinder, and been afterwards open to an exhaust, hot gases are passed through to clean and dry it, and while the chamber is still full of hot dry gases it is closed. Steam at a suitable pressure is now admitted, mixing there with the hot gases, and forming the working mixture for use in the cylinder. This mixture, being at a high pressure, expands in the cylinder, which, after the former has done duty in effecting a stroke of the piston, is opened to the exhaust, and the spent mixture allowed to escape. For a single-acting engine one mixing chamber is said to suffice, while a double-acting engine requires at least two, in each of which the process takes place; but the chamber or chambers to supply actuating fluid to one end of the cylinder, or of each cylinder, must be separate from those that supply the other end, in order to allow ample time for the process of cleaning out, drying, and filling with hot gases, admitting steam, etc.

BRIGHT STORIES.

THE SNOWSTORM.

From the Russian of Alexander Pushkin.

Toward the end of 1811, at a memorable period for Russians, lived on his own domain of Nenaradova the the kind hearted Gavril R. He was celebrated in the whole district for his hospitality and his genial character. Neighbors constantly visited him to have something to eat and drink and to play at five copeck boston with his wife, Praskovia. Some, too, went to have a look at their daughter, Maria, a tall, pale girl of seventeen. She was an heiress, and they desired her either for themselves or for their sons.

Maria had been brought up on French novels, and consequently was in love. The object of her affection was a poor ensign in the army, who was now at home in his small village on leave of absence. As a matter of course, the young man reciprocated Maria's passion. But the parents of his beloved, noticing their mutual attachment, forbade their daughter even to think of him, while they received him worse than an ex-assize judge.

Our lovers corresponded, and met alone daily in the pine wood or by the old roadway chapel. There they vowed everlasting love, inveighed against fate, and exchanged various suggestions. Writing and talking in this way, they quite naturally reached the following conclusion :

If we cannot exist apart from each other, and if the tyranny of hard hearted parents throws obstacles in the way of our happiness, then can we not manage without them ?

Of course this happy idea originated in the mind of the young man, but it pleased immensely the romantic imagination of Maria.

Winter set in and put a stop to their meetings, but their correspondence became all the more active. Vladimir begged Maria in every letter to give herself to him that they might get married secretly, hide for a while and then throw themselves at the feet of their parents, who would, of course, in the end be touched by their heroic constancy and say to them, "Children, come to our arms !"

Maria hesitated a long while, and out of many different plans proposed that of flight was for a time rejected. At last, however, she consented. On the appointed day she was to decline supper and retire to her room under plea of headache. She and her maid, who was in the secret, were then to go out in the garden by the back stairs, and beyond the garden they would find a sledge ready for them, would get into it and drive a distance of five miles from Nenaradova to the village of Jadrino straight to the church, where Vladimir would be waiting for them.

On the eve of the decisive day Maria did not sleep all night ; she was packing and tying up linen and dresses. She wrote, moreover, a long letter to a friend of hers, a sentimental young lady, and another to her parents. Of the latter she took leave in the most touching terms. She excused the step she was taking by reason of the unconquerable power of love, and wound up by declaring that she should consider it the happiest moment of her life when she was allowed to throw herself at the feet of her dearest parents. Sealing both letters with a Toula seal, on which were engraved two flaming hearts with an appropriate inscription, she at last threw herself upon her bed before daybreak, dozed off, though even then she was awakened from one moment to another by terrible thoughts. First it seemed to her that at the moment of entering the sledge in order to go and get married, her father stopped her, and with cruel rapidity dragged her over the snow, and threw her into a dark, bottomless cellar —down which she fell headlong with an indescribable sinking of the heart. Then she saw Vladimir lying on the grass, pale and bleeding ; with his dying breath he implored her to make haste and marry him. Other hideous and senseless visions floated before her one after another. Finally she rose paler than usual, and with a real headache.

Both her father and her mother remarked her indisposition. Their tender anxiety and constant inquiries, "What is the matter with you, Masha—are you ill?" cut her to the heart. She tried to pacify them and appear cheerful, but she could not. Evening set in. The idea that she was passing the day for the last time in the midst of her family oppressed her. In her secret heart she took leave of everybody, of everything which surrounded her.

Supper was served ; her heart beat violently. In a trembling voice she declared that she did not want any supper, and wished her father and mother good night. They kissed her, and as usual blessed her, and she nearly wept.

Reaching her own room she threw herself into an easy chair and burst into tears. Her maid begged her to keep calm and take courage. Everything was ready. In half an hour Masha would leave forever her parent's home, her own home, her peaceful life as a young girl.

Out of doors the snow was falling fast, the wind howling. The shutters rattled and shook. In everything she seemed to recognize omens and threats.

Soon the whole house was quiet and asleep. Masha wrapped herself in a shawl, put on a warm cloak, and with a box in her hand passed out on to the back staircase. The maid carried two bundles after her. They descended into the garden. The snowstorm raged ; a strong wind blew against them, as if trying to stop the young culprit. With difficulty they reached the end of the garden. In the road a sledge awaited them.

The horses, from cold, would not stand still. Vladimir's coachman was walking to and fro in front of them, trying to quiet them. He helped the young girl and her maid to their seats, and packing away the bundles and dressing case, took up the reins, and the horses flew forward into the darkness of the night.

Having entrusted the young lady to the care of fate and of Tereshka, the coachman, let us return to the young lover.

Vladimir had spent the whole day in driving. In the morning he had called on the Jadrino priest and with difficulty came to terms with him. Then he went to seek the witnesses from among the neighboring gentry. The first on whom he called was a former cornet of horse, Dravin by name, a man in the forties, who consented at once. The adventure, he declared, reminded him of old times and of his larks when he was in the Hussars. He persuaded Vladimir to stop to dinner with him, assuring him that there would be no difficulty in getting the other two witnesses. Indeed, immediately after dinner in came the surveyor, Schmidt, with a moustache and spurs, and the son of a captain-magistrate, a boy of sixteen, who had recently entered the Uhlans. They not only accepted Vladimir's proposal, but even swore that they were ready to sacrifice their lives for him. Vladimir embraced them with delight, and drove off to get everything ready.

It had long been dark. Vladimir despatched his trustworthy Tereshka to Nenaradova with his two-horsed sledge, and with appropriate instructions for the occasion. For himself he ordered the small sledge with one horse and started alone, without a coachman, for Jadrino, where Maria ought to arrive in a couple of hours. He knew the road and the drive would only occupy twenty minutes.

But Vladimir had scarcely passed from the enclosure into the open field when the wind rose, and soon there was a driving snowstorm, so heavy and so severe that he could not see. In a moment the road was covered with snow. All landmarks disappeared in the murky yellow darkness, through which fell white flakes of snow. Sky and earth became merged into one. Vladimir, in the midst of the field, tried in vain to get to the road. The horse walked on at random, and every moment stepped either into deep snow or into a rut, so that the sledge was constantly upsetting. Vladimir tried at least not to lose the right direction, but it seemed to him that more than half an hour had passed, and he had not reached the Jadrino woods. Another ten minutes passed and still the wood was invisible. Vladimir drove across fields intersected by deep ditches. The snowstorm did not abate and the sky did not clear. The horse was getting tired, and the perspiration rolled from him like hail, in spite of the fact that every moment his legs were disappearing in the snow.

At last Vladimir found that he was going in the wrong direction. He stopped, began to reflect, recollect and consider, till at last he became convinced that he ought to have turned to the right. He did so now. His horse could scarcely drag along. But he had been more than an hour on the road, and Jadrino could not now be far. He drove and drove, but there was no getting out of the field. Still snowdrifts and ditches. Every moment the sledge was upset, and every moment Vladimir had to raise it up.

Time was slipping by, and Vladimir grew seriously anxious. At last in the distance some dark object could be seen. Vladimir turned in its direction, and as he drew near found it was a wood.

"Thank Heaven !" he thought, "I am near the end."

He drove by the side of the wood, hoping to come at once upon the familiar road, or, if not, to pass round the wood. Jadrino was situated immediately behind it.

He soon found the road and passed into the darkness of the wood, now stripped by the winter. The wind could not rage here; the road was smooth, the horse picked up courage, and Vladimir was comforted.

He drove and drove, but still Jadrino was not to be seen ; there was no end to the wood. Then, to his horror, he discovered that he had got into a strange wood. He was in despair ; he whipped his horse, and the poor animal started off on a trot, but it soon got tired; and in a quarter of an hour, in spite of poor Vladimir's efforts, could only crawl.

Gradually the trees became thinner, and Vladimir drove out of the wood, but Jadrino was not to be seen. It must have been about midnight. Tears gushed from the young man's eyes. He drove on at random, and now the weather abated, the clouds dispersed, and before him was a wide stretch of plain, covered with a white, billowy carpet. The night was comparatively clear, and he could see a small village a short distance off, which consisted of four or five cottages. Vladimir drove towards it. At the first door he jumped out of the sledge, ran up to the window and tapped.

After a few minntes a wooden shutter was raised, and an old man stuck out his gray beard.

"What do you want ?"

"How far is Jadrino ?"

"How far is Jadrino ?"

"Yes, yes. Is it far ?"

"Not far ; about ten miles."

At this answer Vladimir clutched hold of his hair and stood motionless, like a man condemned to death.

"Where do you come from ?" added the man. Vladimir had not the courage to reply.

"My man," he said, "can you procure me horses to Jadrino ?"

"We have no horses," answered the peasant.

"Could I find a guide ? Will pay him any sum he likes."

"Stop," said the old man, dropping the shutter. "I will send my son out to you ; he will conduct you."

Vladimir waited. Scarcely a minute had passed when he again knocked. The shutter was lifted and a beard was seen.

"What do you want?"

"What about your son?'

"He'll come out directly; he is putting on his boots. Are you cold? Come in and warm yourself."

"Thanks; send out your son quickly"

The gate creaked; a youth came out with a cudgel and walked on in front, at one time pointing out the road, at another looking for it in a mass of drifted snow.

"What o'clock is it?" Vladimir asked him.

"It will soon be daylight," replied the young peasant. Vladimir spoke not another word.

The cocks were crowing, and it was light when they reached Jadrino. The church was closed. Vladimir paid his guide and drove into the yard of the priest's house. In the yard his two-horse sledge was not to be seen. What news awaited him?

But let us return to the kind proprietor of Nenaradova, and see what is going on there.

Nothing.

The old people awoke and went into the sitting-room, Gavril in a nightcap and flannel jacket. Praskovia in a wadded dressing-gown. The samovar was brought in, and Gavril sent the little maid to ask Maria how she was and how she had slept. The little maid returned, saying that her young lady had slept badly, but that she was better now, and that she would come into the sitting-room in a moment; and, indeed, the door opened and Maria came in and wished her papa and mamma good morning.

"How is your headache, Masha?" (familiar for Mary), inquired Gavril.

"Better, papa," answered Masha.

"The fumes from the stoves must have given you your headache," remarked Praskovia.

"Perhaps so, mamma," replied Masha.

The day passed well enough, but in the night Masha was taken ill. A doctor was sent for from town. He came towards evening and found the patient delirious. Soon she was in a severe fever, and in a fortnight the poor patient was on the brink of the grave.

No member of the family knew anything of the flight from home. The letters written by Masha the evening before had been burnt, and the maid, fearing the wrath of the master and mistress, had not breathed a word. The priest, the ex-cornet, the big mustached surveyor, and the little lancer were equally discreet, and with good reason. Tereshka, the coachman, never said too much, not even in his drink. Thus the secret was kept better than it might have been by half a dozen conspirators.

But Masha herself, in the course of her long fever, let out her secret. Nevertheless, her words were so disconnected that her mother, who never left her bedside, could only make out from them that her daughter was desperately in love with Vladimir, and that probably love was the cause of her illness. She consulted her husband and some of her neighbors, and at last it was decided unanimously that the fate of Masha ought not to be interfered with, that a woman must not ride away from the man she is destined to marry, that poverty is no crime, that a woman has to live not with money but with a man, and so on. Moral proverbs are wonderfully useful on such occasions, when we can invent little or nothing in our own justification.

Meanwhile the young lady began to recover. Vladimir had not been seen for a long time in the house of Gavril, so frightened had he been by his previous reception. It was now resolved to send and announce to him the good news which he could hardly expect—the consent of her parents to his marriage to Maria.

But what was the astonishment of the proprietors of the Nenaradova when, in answer to their invitation, they received an insane reply. Vladimir informed them he could never set foot in their house, and begged them to forget an unhappy man whose only hope now was in death. A few days afterwards they heard that Vladimir had left the place and joined the army.

A long time passed before they ventured to tell Masha, who was now recovering. She never mentioned Vladimir. Some months later, however, finding his name in the list of those who had distinguished themselves, and been severely wounded at Borodino, she fainted, and it was feared that the fever might return. But, heaven be thanked! the fainting fit had no bad results.

Maria experienced yet another sorrow. Her father died, leaving her the heiress of all his property; but the inheritance could not console her. She shared sincerely the affliction of her mother, and vowed she would never leave her.

Suitors clustered round the charming heiress, but she gave no one the slightest hope. Her mother sometimes tried to persuade her to choose a companion in life, but Maria shook her head and grew pensive.

Vladimir no longer existed. He had died at Moscow on the eve of the arrival of the French. His memory was held sacred by Maria, and she treasured up everything that would remind her of him—books he had read, drawings which he had made, songs which he had sung, and the pieces of poetry which he had copied out for her.

The neighbors, hearing all this, wondered at her fidelity, and awaited with curiosity the arrival of the hero who must in the end triumph over the melancholy constancy of this virgin Artemis.

(*Concluded next week.*)

DOMESTIC DIETETICS.

SPECIALLY PREPARED, FROM PRACTICAL TESTS, FOR THE LADY READERS OF THE "AMERICAN ANALYST."

SEASONABLE FOOD.

September.

GAME AND POULTRY.—Pigeon, chicken, duck, woodcock.

MEATS.—Beef, mutton, lamb, veal, ham, kidneys, liver, venison.

FRUITS.—Apples, bananas, blackberries, gooseberries, huckleberries, grapes, melons, oranges, peaches, pears, pineapple, plums, raspberries, currants.

FISH.—Bass, blackfish, bluefish, clams, cod, crabs, eels, flounders, halibut, herrings, lobster, mackerel, mussels, porgie, prawn, rockfish, salmon, trout, sea-bass, sturgeon, turtle, white fish, whiting.

VEGETABLES.—Beets, beans, cabbage, carrots, cauliflower, corn, cucumbers, egg-plant, garlic, lettuce, onions, parsley, parsnips, potatoes, radishes, rhubarb, savoy, shallots, spinach, squash, tomatoes, turnips.

PRACTICAL RECIPES.

TOMATO SOUP.—Cover a good sized soup bone with cold water and add two onions. When the meat falls from the bone add sufficient water to make four quarts and take out the bone and onion. Let it get cold, then remove the grease and add a can of tomatoes or a quart of fresh ones, a teaspoonful of sugar, a tablespoonful of corn-starch and butter rubbed together, salt and pepper. Boil for a few minutes and serve.

CANNED APPLES.—Peel six pounds of winter pippins and cut them in halves; put them in a stone jar and mix half their weight of sugar with them, and let them stand for a day and a half; then transfer them to the preserving kettle; pour a pint of water over them and let them boil slowly for an hour or so, until they are tender and clear; then slice an orange very thin and let it cook a few minutes with the apples. Fill your jars and seal them.

CREAM MAYONAISE.—One table-spoonful each of dry mustard, salt, sugar, melted butter, yolks of two eggs; mix all together. Then add one cupful of sweet cream, and lastly, one cupful of vinegar. Boil like boiled custard.

RASPBERRY VINEGAR.—Put one pint of vinegar over two quarts of raspberries and let them lie together two or three days. Mash them up and squeeze through a bag. To each pint of juice allow a pound of sugar and boil them together for twenty minutes, carefully removing the scum as it rises. Bottle when it is cold.

COFFEE JELLY.—Put seven table-spoonfuls of freshly ground coffee into the coffee pot, and mix into it the white of an egg and half a cup of cold water. Put the pot on the fire and add a quart of boiling water; beat up for a minute, then cover and let boil for twenty minutes, stirring now and then. Set off the stove, pour in half a cup of cold water and let the coffee settle. In the meantime let half a box, or one ounce of gelatine soak in one-half a cup of cold water or coffee for two hours; when the coffee is settled, add it to the gelatine and stir until the latter is thoroughly dissolved, sweeten to taste, pour into a quart bowl and set away to stiffen. Serve very cold in a glass dish, with whipped cream heaped about it.

CREAM RICE PUDDING.—Put one quart of sweet milk into a pudding dish, and set it on the back of the stove. Wash and pick over three heaping teaspoonfuls of rice and add them to the milk. Let this stand where it will be slightly warm for four or five hours, until the rice has swelled; stir frequently. Add a teaspoonful of butter, a small half cup of sugar, half a teaspoonful of salt, some nutmeg, a teaspoonful of vanilla, and bake slowly for about half an hour or until it is thick and creamy. Let it be very cold before eating.

POTATO ROLLS.—Boil six potatoes and mash them, add two cupfuls of milk, one table-spoonful of butter, the beaten yolks of three eggs, salt. When the mixture is cold, add a teaspoonful of yeast and enough flour to make it stiff; beat well, let rise, form into rolls, rise again, and bake a delicate brown.

ORIENTAL COOKERY.

PILLAU, MULLAGATAWNY AND CURRIE.

The perfect cook is a true eclectic philosopher. He aims at taking the best from the culinary wisdom and lore of each country, and thus eventually concentrates in one complete system the maxima of what is good and wholesome. We cannot but think that, generally regarded, too little attention has been paid by ourselves to Oriental cookery, whence it is quite certain much might be drawn out that would be to many among us a new table delight, besides being the acquisition of not a few thoroughly wholesome dishes to our menus. The subjoined unique collection of practical recipes for sundry forms of Oriental cookery we are pleased to place before our readers, some of whom may perhaps be enabled thereby to add not a few rarities and really appetizing and attractive dishes to their bills of fare. The first item relates to the national dish, the Turkish pillau. The recipes for Hindoo and Mussulman cookery are quite distinct one from another, the one being mostly vegetarian—or, indeed, wholly so—while the latter use meat freely. When the native asks you to partake of fowl, mutton, beef, or game, he means the pillau flavored with it, for, whatever it may be, it rarely makes its appearance in its original state, and is generally boiled so long that all the flavor goes to the rice. Pillaus, when properly cooked, are most tasty and nourishing—delightful both to the organs of taste and smell; but, if ill cooked, there is nothing more disagreeable and disgusting. Take plain boiled rice for an example: if ill cooked, can there be anything more disgusting than the sticky mess it presents; while, on the other hand, if cooked with care, there is nothing more nutritious, delicious and tempting,—and it can be eaten with anything either sweet or savory.

CHICKEN PILLAU.

Get a nice fat young fowl, put it into a saucepan with about two quarts of water, a large onion (whole),

three or four cloves of garlic, also whole, four bay leaves, twenty-four cloves, two sticks of cinnamon, a blade of mace, the seeds of twelve cardamums, one teaspoon of salt; boil till the fowl is tender. Now remove the fowl, and put into the liquor one pound of the best Patna rice; stir occasionally; watch it narrowly. The moment the rice is soft drain it through a wire sieve (do not waste the liquor, for it makes delicious soup); steam it before the fire for about half an hour or so. Before serving remove the onion, garlic, bay leaves, cinnamon, and mace, but not the cloves and cardamum. Put your fowl on a dish, cover it over with the rice, and garnish it with fried almonds, raisins, and hard-boiled eggs, also onions fried brown and crisp. If you wish for a more savory dish still, cut your fowl into joints, and dust it over with currie powder and spice. Put two ounces of butter into a frying-pan with an onion sliced very thin. When the onion is brown, put in the jointed fowl and fry. Serve in the same way as the above. Both ways of cooking the pillau are delicious.

SWEET PILLAU.

Boil one pound of the best Patna rice in two quarts of strong white stock, without any seasoning whatever except a pinch of salt. Watch your rice carefully; the moment it is tender, drain and steam before the fire. Now prepare a syrup flavored with whatever you like. In India the usual flavoring is lemon, cocoanut, musk, or rose water. Turn the rice into a dish, put a little piece of the best butter in it, stir it lightly with a fork, for the butter to mix with it, then pour over your syrup. Garnish the top with fried almonds or pistachios and sultanas. If preferred, the rice may be colored with a little saffron—a thing very much used in India for all dishes made of rice.

MULLAGATAWNY SOUP.

Make a good strong stock of shin of beef, about two quarts or more. Cut up an onion into very thin rings, put it in a saucepan with two ounces of butter; fry a golden brown; now put in one heaped-up table-spoonful of currie powder; fry a minute longer; then add your stock, twelve cloves, the seeds of twelve cardamums, three bay leaves, a sprig of tarragon and chervil, three cloves of garlic, a teaspoonful of salt. Boil for about twenty minutes, then add two ounces of Edwards' New Tomato Soup, which gives the mullagatawny a most delicious flavor. Leave it on the hob for about two hours; do not let it boil, but very gently simmer. Before serving, strain the soup, and add either the juice of half a lemon or a table-spoonful of tamarinds pulped in a little warm water and strained. The tamarind gives a peculiar flavor of its own that is very highly approved of.

WHITE MULLAGATAWNY.

This is a soup very well suited for fast days—and is nourishing withal. Cut up an onion into thin rings, fry it in two ounces of butter a golden color, then add a teaspoonful of currie powder, and a table-spoonful of the best currie paste, and then one quart of water, twelve cloves, the seeds of twelve cardamums, three bay leaves, three cloves of garlic; let it boil up, then add two ounces of Edwards' White Vegetable Desiccated Soup; boil until the soup thickens, then add one quart of milk, stir well, salt to taste, set it on the hob to simmer gently. Before serving, strain, and serve with a separate dish of boiled rice, and lemons cut in slices. If preferred, this soup can be made with best stock instead of milk, but in either case thicken with Edwards' White Desiccated Soup, which is invaluable for Indian cookery, such as soups and curries, etc.

DHAL CURRIE.

Boil half a pint of lentils in one quart of water till quite soft and pulpy; set them aside. Now cut up an onion into thin rings, fry in two ounces of butter, and add to it the currie powder, and all the flavorings as for other curries. Then put in your lentils, let it boil for about an hour, and serve with a dish of plain boiled rice.

PLAIN DHAL.

Boil some lentils as for the above recipe; put them aside. Cut up an onion into thin rings, fry a delicate golden color in two ounces of butter. Now add your lentils, twelve cloves, two cloves of garlic chopped very fine, the seeds of twelve cardamums, three bay leaves, and salt to taste. Boil for about half an hour; serve with a dish of plain boiled rice separately, and lemons cut in slices. This a favorite Anglo-Indian breakfast dish.

LARKS OR PIGEONS—INDIAN STYLE.

Prepare your birds as for roasting; pass half a pound of the best beef through a mincing machine; now chop up an onion, two cloves of garlic, a sprig of tarragon and chervil, two bay leaves, very fine; fry all in two ounces of butter, then add a spoonful of the best currie powder, stir, and then add your mince; let it cook till the mince is done through. Now stuff your birds with the mixture and roast them a good color, basting them with butter mixed with a little currie powder or paste. When done, dish them prettily with salads of all kinds as a garnish, or, if liked, with gravy on toast, with a good tomato-sauce gravy flavored with currie paste. This is a delicious dish. Teal and quail can be dressed in the same way.

CURRIE PUFFS.

Make a puff paste in the usual way, roll it out as for jam turnovers, fill it with the following forcemeat, and make it in the shape of jam tarts; fry them in butter till they are a pale golden brown, put them on paper to drain the fat off, and serve with fried crisp parsley.

FORCEMEAT FOR THE ABOVE.

Half pound of the best beef passed through a machine; cut up an onion into thin rings, fry a nice color, add a table-spoonful of currie powder, and then your meat, the seeds of twelve cardamums, twelve cloves, two cloves of garlic chopped very fine, and salt to taste. These puffs are delicious.

INSOMNIA.

SOME OF THE CIRCUMSTANCES THAT DO MURDER SLEEP.

Inability to sleep is about as unnatural a condition as can be imagined, and one that has been engendered by unnatural ways of living. The causes are so various that no special plan of treatment would suit all cases; and permanent relief can only be obtained through the general adjustment of one's habits to the accepted laws of hygiene. In this respect, regularity—in meals, in taking exercise, in rising and retiring—is an important factor. To practice going to bed early one night and late the next, sleeping one night eight or ten hours and another perhaps only three or four, and continuing this for any length of time, is almost sure to produce sleeplessness that will shortly become chronic and very difficult to overcome. Some, indeed, are so sensitive to any irregularity that a single infraction of the regular rule for retiring will prevent sleep, not only on the special night, but sometimes for succeeding nights also. Gentle calisthenic exercise taken just before retiring, or a sponge bath followed by brisk rubbing with a coarse towel, will usually prevent this restlessness from becoming chronic. One of the chief causes of sleeplessness is a sedentary mode of life. The bodily functions respond to the natural stimula of fresh air, light and exercise, and when these are withheld the result is sleeplessness at night. Nothing conduces so greatly to healthy slumber as abundant exercise in the open air; and this should be the first remedy tried in cases of wakefulness that threaten to become habitual. A good brisk walk taken an hour or two before bedtime, preferably with a pleasant companion, or, if alone, with some object in view besides mere exercise, and always avoiding unpleasant thoughts, will usually furnish the stimulus required. Dancing, cycling, or any form of exercise which quickens the sluggish circulation and sends the blood to the surface of the body, thus relieving the brain, is conducive to sleep. If those engaged in business, especially of the class demanding close mental application, could exert the will power necessary to entirely banish all thoughts of their work when it is ended for the day, the insomnia that has almost become a national malady would speedily decrease. The respite from care, for even a few hours, will reinvigorate the brain, and work will be taken up with new energy each succeeding day. The more complete the relaxation the more beneficial will be the result. If before restlessness at night becomes habitual wakefulness, the sufferer would realize the danger and discover the cause—whether it be want of exercise or fresh air, improper food, too close application, or insufficient recreation—and persevere in some simple remedy, nine times out of ten—unless there is some organic difficulty—the tendency to insomnia might be arrested. Alcoholic liquors and drugs should never be resorted to. They may induce sleep, but the habit once formed it will be found impossible to sleep without their aid, and in increasing doses. If any stimulant be desired, a glass of hot milk is preferable, in every way, to liquors and narcotics. Many persons have found a glass of cold milk and a cracker, taken just before going to bed, very efficacious in promoting sleep. A glass of lemonade, not too strong and not sweet, is another simple soporific. Moderate warmth also induces sleep, especially in winter; sleeplessness is often the penalty paid for getting into bed with cold feet and hands. A warm bath taken just before going to bed is efficacious even in quite obstinate cases of sleeplessness, and has the advantage of being quite harmless. Always rub briskly with a brush or coarse towel, to bring the blood to the surface, thus relieving the brain. Whenever possible, persons inclined to wakefulness should sleep alone, and from a hygienic point of view separate beds are always preferable for both adults and children. The bed should be moderately hard (never feathers), turned and thoroughly aired every day, the bed clothing light in weight and only sufficient to maintain a natural degree of warmth. Soft wool blankets are best. A good bed in a well-ventilated room, good food of the right sort, in proper quantities and at proper times, good air, regular bathing, sufficient exercise to produce a pleasant weariness, congenial occupation, absolutely regular habits, strict avoidance of stimulants and narcotics, a clear conscience, and the exercise of sufficient will power, will in time overcome the most obstinate case of insomnia.—*Demorest's Magazine, September.*

PHOSPHORESCENCE.

THE PHENOMENON ATTRIBUTED TO LUMINOUS BACILLI.

Published discussions and treatises on this subject have for the most part been confined so exclusively to disease germs, that for the average reader the mere mention of the term "bacilli" is sufficient to conjure up visions of cholera, diphtheria, tuberculosis, and other of the many ills which flesh is heir to. Nevertheless, the history of disease germs is but a small branch of the science of bacteriology, which embraces the study of an infinite variety of life forms, some of which are simply innocuous to higher organisms, others essential to their well-being, and all deserving of careful study. Among the many interesting types in this world of life laid bare by the microscope are those which generate light, and to these I propose to confine myself in the present papers. The readers of this magazine will remember that in a previous article the bacteria were said to have been classed according to their shapes as spherical, cylindrical, and spiral; the luminous creatures with which we are now con-

cerned belong to the cylindrical or bacilli type. It is a matter of common observation that raw flesh or fish exhibits a greenish luminous appearance in the dark. This luminosity is due to the presence of a bacillus to which the name "Bacterium phosphorescence" has been given. Under the microscope it exhibits itself as a short, thick staff, rounded and stiff at both ends. The luminous bacillus is very widely diffused. The readiest means for investigating it are to institute researches in fresh sea-fish. Take some fresh herrings or other sea-fish, place them in a covered dish, or between two plates, at a temperature of 60 deg. or upward, and after an interval of frequently not more than twenty-four hours, luminous spots will appear on the surface of the fish and spread rapidly, covering the whole fish in the course, generally, of the second day. If we now leave the fish uncared for, putrescence, due to the action of the bacteria, will set in, and as it extends, the beautiful pale-green phosphorescence disappears. The luminous bacilli which flourished for a time under conditions favorable to their well-being, have gone down in the struggle for existence with another set of bacteria better adapted to the newly evolved conditions. The phosphorescent bacilli can, however, be transplanted amid conditions favorable to their persistence. They have been transferred to glass tubes containing gelatine solution, in which they thrive and afford opportunities for the study of their life history. The luminous bacilli thrive at temperatures as low even as from 32 deg. to 60 deg. Fahr., but temperatures between 60 deg. and 80 deg. are more favorable to their development. They can exist in an atmosphere containing oxygen, or in one free from it; but in the absence of oxygen luminosity is not generated. If we prepare a test tube in such a manner that its inner wall is covered with only a very thin sheet of gelatine, the whole surface is covered so thoroughly with the inserted bacilli, and the tube becomes so luminous, that the figures on a watch may be read and the hands seen by its light. Indeed, one bacteriologist has suceeded in photographing the phosphorescent bacilli by their own light. These experiments also afford evidence of the modification of bacilli by change of environment, a fact which plays so important a feature in the system of inoculation as a remedial measure in disease. At first the phosphorescent bacilli flourish vigorously in the gelatine, and will even maintain their luminosity for months, but if we continue to transfer them from generation to generation to fresh gelatine, the luminosity gradually disappears. Immediately after each transplantation into a new medium the luminosity reappears with subdued brilliancy, but the power of generating it is lost in a few days. It can, however, be restored to its pristine vigor by the addition of two or three per cent. of common salt to the gelatine, from which we gather that natural or artificial sea-water or boiled fish favor the appearance of phosphorescence. The sea is especially the home of phosphorescent organisms, and here, too, the phosphorescent bacillus has his home. Prof. Fisher has discovered in West Indian waters a new bacillus which differs very materially from the one above described. He is more slender, more lively in his movements, and instead of a greenish, emits a bluish phosphorescence. He has been named "West Indian luminous bacillus," to distinguish him from the more familiar one above described. He, too, can be propagated in gelatine in test tubes, but he has his own peculiarities. A true child of the Tropics he will not flourish at a temperature below 60 deg. Fahr., and it is only at a temperature of 86 deg. or upward that he shows vigorous life, fecundity, and brilliancy. "The best conditions for studying him," says Prof. Karl Frankel, in his *Grundriss der Bakterien Kunde*, "is unquestionably on the surface of boiled fish. By inoculating this with an artificial culture of the bacillus it will be found covered in a few hours with a thriving colony which, in the dark, throws off a beautiful bluish light." Even our German waters have their characteristic luminous bacilli. Prof. Fisher has discovered one in Kiel harbor which reminds one, in many respects, of his West Indian congener. Like him, he is full of animation, and radiates similarly a bluish-white light, but he has his own especial idiosyncrasies which have been held to justify his recognition as a distinct species under the name of "native luminous bacillus." He is a true child of the North, and in contradistinction to his West Indian congener, he finds himself in his life-element at a temperature below 60 deg., at which the vitality of his tropical congener is suspended. Indeed, he can stand a cold below zero and shed his bluish-white light around a freezing point. To the numerous species of luminous living creatures which animate earth, and sea, and air, science has now added three of the most diminutive. But the method or process by which all these creatures generate their light is still hidden behind an impenetrable veil, which science has hitherto striven in vain to lift.—*Die Gartenlaube, Leipsic.*

STORM CLASSIFICATION.

THE NOMENCLATURE OF ATMOSPHERIC DISTURBANCES.

A correspondent of the *Tribune* having inquired what is the difference between a cyclone and a tornado, that journal turns its weather side to the subject to the following interesting and instructive effect: Cyclones and tornadoes are both wind storms, with more or less rain, and they both whirl; otherwise, they are very unlike. The cyclone is from 200 to 1,500 miles across, is generally born at sea, does most of its work there, and lasts several days, sometimes even weeks, before dying out. Its extent is so great that it takes many hours, and often a day or two, to pass a given point; and though there is a gradual change of direction, the wind blows apparently as a straight-line gale. The tornado is a land storm, measuring only a few hundred feet in diameter. The whole thing can be discerned at a glance. It sweeps over a narrow

Buffalo Lithia Water, Spring No. 2, in Bright's Disease, Gout, Stone in the Bladder, and Diseases Generally of Uric Acid Diathesis, Etc., Etc.

DR. WM. A. HAMMOND, of Washington, D. C., Surgeon General U. S. Army (retired), Professor of Diseases of the Mind and Nervous System in the University of New York, etc.

"I have for some time made use of the BUFFALO LITHIA WATER in cases of AFFECTIONS of the NERVOUS SYSTEM, complicated with BRIGHT'S DISEASE OF THE KIDNEYS or with a GOUTY DIATHESIS. *The results have been eminently satisfactory.* Lithia has for many years *been a favorite with me in like cases, but the* BUFFALO WATER CERTAINLY ACTS BETTER THAN ANY EXTEMPORANEOUS SOLUTION of THE LITHIA SALTS, and is, moreover, better borne by the stomach. I also often prescribe it in those cases of CEREBRAL HYPERÆMIA resulting from OVER MENTAL WORK—in which the condition called NERVOUS DYSPEPSIA exists—*and generally with* MARKED BENEFIT."

DR. WM. B. TOWLES, Professor of Anatomy and Materia Medica, in the Medical Department of the University of Virginia.

"BUFFALO LITHIA SPRINGS, No. 2, belongs to the ALKALINE or, *perhaps, to the* ALKALINE SALINE Class, *for it has proved far more efficacious in many diseased conditions than any of the simple* ALKALINE waters.

"*I feel no hesitancy whatever in saying that in* GOUT, RHEUMATIC GOUT, RHEUMATISM, STONE *in the* BLADDER, and in all diseases of URIC ACID DIATHESIS, *I know of no remedy at all comparable to it.*

"*Its effects are marked in causing a disappearance of* ALBUMEN *from the urine. In a* single case of BRIGHT'S DISEASE *of the* KIDNEYS, I witnessed *decided beneficial results from its use, and from its action in this case I should have great confidence in it as a remedy in certain stages of this disease.* In DYSPEPSIA, especially that form of it in which there *is an excessive preauction of* ACID *during the process of nutrition*, in some of the PECULIAR AFFECTIONS *of* WOMEN, notably in SUPPRESSION of the MENSES, and in CHRONIC MALARIAL POISONING, etc., I have found it highly efficacious."

DR. G. HALSTEAD BOYLAND, late Professor of Surgery, Baltimore Medical College, late Surgeon French Army (Decorated), Member Baltimore Academy of Medicine, Member of American Medical Association.

"In BRIGHT'S DISEASE of the KIDNEYS, ACUTE or CHRONIC, BUFFALO LITHIA WATER, Spring No. 2, is, in my experience, *without a rival*, whether in the PARENCHYMATOUS form or INTERSTITIAL NEPHRITIS. In cases in which the ALBUMEN in the URINE reached as high as 50 per cent., I have known it under a course of this water gradually diminish and finally disappear, at the same time other alarming symptoms were relieved and the sufferers restored to health.

"In STONE in the BLADDER of the RED LITHIC ACID and the WHITE PHOSPHATIC DEPOSIT, the SOLVENT power of this water is *unmistakable.*"

Water in cases of one dozen half gallon bottles, $5.00 f. o. b. here.

THOS. F. GOODE, Proprietor, BUFFALO LITHIA SPRINGS, VA.

track, and does its work in a city as large as Louisville almost in an instant. Its whole lifetime, during which it may have traveled twenty-five or fifty miles, is seldom over an hour or two, often less. It is apt to have thunder-shower accompaniments—gusts, rain or hail and lightning; but its most obvious characteristic is a funnel-shaped cloud descending like the slack of a balloon, or an elephant's trunk, from the main thunder-cloud. This vapor-spout is the axis of the "twister." In considering both cyclones and tornadoes, the rate of progress is much less important than the gyratory velocity. In a cyclone the latter is 100 miles an hour, sometimes, near the centre, the violence being enhanced by the rather gusty character of the protracted gale. The tornado whirls at a rate variously estimated from 500 to 2,000 miles an hour. Though ephemeral and diminutive, it has vastly greater violence. To call it a "cyclone" is to belittle its terrors. True cyclones are exceedingly scarce, while tornadoes are numbered by the hundred every season. Cyclones are of tropical origin, and are chiefly found in five localities—the West Indies, Bengal Bay, and the Chinese coast, north of the equator; and in the South Indian Ocean off Madagascar, and the South Pacific near Samoa. In the Antilles there are not half a dozen on the average every season. They usually come only between July and October. For the term "cyclone," then, the news-gatherer has but little legitimate use. "Hurricane" is the old Spanish name for a West Indian cyclone; but it is now used also to designate a long-continued wind of extreme violence. In Beaufort's scale one rises through "light," "gentle," "fresh" and "strong breezes," "fresh," "strong" and "whole gales" and "storm," to "hurricane," by which the mariner understands "a velocity of ninety miles or more an hour." For a short, sudden blast, such as often comes in a summer storm and wrecks a yacht, levels trees, unroofs buildings, and works other like damage, "squall" is the proper term, unless there is good evidence of a rotary motion and a funnel-shaped cloud. Nor will the intelligent reporter deem "squall" inadequate for his purposes when he recalls that the British man-of-war Eurydice, with officers and crew, suddenly capsized and sunk (March 24, 1878) in a storm of this type.

Exhaustion

Horsford's Acid Phosphate.

The phosphates of the system are consumed with every effort, and exhaustion usually indicates a lack of supply. The Acid Phosphate supplies the phosphates, thereby relieving exhaustion, and increasing the capacity for labor. Pleasant to the taste.

Dr. A. N. KROUT, Van Wert, O., says:
"Decidedly beneficial in nervous exhaustion."

Dr. S. T. NEWMAN, St. Louis, Mo., says:
"A remedy of great service in many forms of exhaustion."

CAUTION:—Be sure the word "Horsford's" is *printed* on the label. All others are spurious. Never sold in bulk.

BUSINESS NOTES.

ARISING AS BY MAGIC.

On the shores of Lake Kampeska, one of the most beautiful of the many lovely sheets of water in South Dakota, and where twelve years ago there was not a white man living within 125 miles, there is to-day in a rich and prosperous agricultural valley of the richest land in the West, Watertown, a city of 6,000 inhabitants, and a better built city than was ever seen in the East of three times its size. As a manufacturing city Watertown is destined to rival Minneapolis and Omaha in a very few years. It is in the centre of the richest farming country of the West, a country which has made thousands of farmers wealthy in one year. A Professor of the State University, writing to a Detroit paper a short time ago, said: "I am standing on the porch of the house of an old friend, who left Michigan five years ago for Watertown, S. D. He arrived in this country with a team of horses, six children, and less than $100 in money. To-day he owns 1,200 acres of the richest and most beautiful land man's eyes ever rested upon. He doesn't owe a dollar, his land is worth $60 to $70 per acre, he has in his granary 8,000 bushels of last year's wheat, will harvest this year 17,000 bushels more, and his fields are covered with the finest stock. From where I am sitting I can see half a dozen other farmers as prosperous as he. In this country the farmer is monarch, the tiller of the soil is king."

SUGAR IS DOWN.

The best of sugar, at the lowest prices, now enables every family to preserve summer fruits for winter use at small expense. Ayer's Preserve Book, just issued, contains the latest and best receipts for canning, preserving, making jellies, catsups, pickles, etc. Ask your druggist for a copy, or send a two-cent stamp to J. C. Ayer Co., Lowell, Mass.

AN OXIDE OF GOLD.—Using a fine sheet of gold as positive electrode in sulphuric acid or nitric acid solution, W. Hampe found that the same became colored brown, and finally a reddish brown powder fell to the bottom of the electrolyzing dish. This was proved qualitatively to be a hydrate of gold formed by the oxidizing action of the electrolytically evolved oxygen. On drying over sulphuric acid, and then heating, it exploded violently.

METEORITE.—Prof. Foote, of Philadelphia, has collected some remarkable meteorites, at Canon Diaplo, Yavapai Co., Arizona. The largest mass weighs 250 lbs., and another 154 lbs. A specimen which he sent to Dr. Koenig was recently described by him before the Academy of Natural Sciences. Dr. Koenig's analysis gave 2 9-10 per cent. nickel, and in the only piece which has yet been cut a cavity was exposed containing small diamonds. As this is the first instance of the occurrence of this gem in meteoric iron, the find will be of great interest to scientists.

PURIFICATION BY COLD.—Pictet, who has taken out a patent for the process, has discovered that from the purest chloroform of commerce, if cooled down to about 70 deg., there separates out a crystalline body, which is then drained from the part which remains liquid. This liquid portion is then exposed to a temperature below 100 deg., when the chloroform itself crystallizes out, and can be separated from an impurity which remains liquid. Chloroform purified in this manner is a colorless liquid, having at 15 deg. the sp. gr. 1.51. It is indefinitely permanent on exposure to light. Whilst the so-called pure chloroform of commerce takes a greenish color if shaken up with a solution of potassium, dichromate and sulphuric acid, if Pictet's chloroform is similarly treated the chromic mixture retains its yellowish color.

ORIGINAL. No. 34.

Small Fresh Fish Baked in a Crust.

BY MRS. D. A. LINCOLN,
Author Boston Cook Book.

Use small fresh fish, like trout, scup, perch, etc. Clean them and wipe dry. Cut gashes one inch apart through the thick flesh on each side. Sprinkle well with salt and pepper. Make a rich crust, with 1 quart flour, into which mix thoroughly 4 level tea sp. Cleveland's baking powder and 1 tea sp. salt. Moisten with thin cream sufficient to make a dough to roll out. Divide into two parts, and roll each part ½ inch thick. Lay the fish on one part, leaving two inches space between each fish. Put the other half of the crust over Cut through the crusts around each fish; pinch the edges together tightly, and lay them some distance apart on a baking tin. Bake about ½ hour. Serve with egg sauce. Cook 1 tea sp. minced onion and 2 table sp. flour in 2 table sp. hot butter, add gradually 1 pint hot milk. Stir as it thickens, and season with 1 tea sp. salt, ⅛ salt sp. white pepper and 1 table sp. lemon juice. Add the chopped whites of three hard boiled eggs, and the yokes mashed and sifted, and serve very hot.—(Copyright, 1891, by Cleveland Baking Powder Co.)

Use only Cleveland's baking powder, the proportions are made for that.

Cleveland's Baking Powder is wholesome, leavens most and leavens best. Try it.

PURE PEPSIN

In Powder and Scale.

MANUFACTURED BY

ARMOUR & COMPANY, Chicago.

Guaranteed free from adulteration or make-weights: of excellent physical properties and high digestive power.

Under similar conditions, **ARMOUR'S PEPSIN** will exhibit greater activity than any other pepsin now before the profession.

The Manufacturers will be pleased to supply members of the Medical Profession with samples of their pepsin, and with full details regarding digestive strength, if desired.

GOLD MEDAL, PARIS 1889.

W. BAKER & Co.'s

Breakfast Cocoa

from which the excess of oil has been removed,

Is Absolutely Pure and it is Soluble.

No Chemicals

are used in its preparation. It has *more than three times the strength* of Cocoa mixed with Starch, Arrowroot or Sugar, and is therefore far more economical, *costing less than one cent a cup.* It is delicious, nourishing, strengthening, EASILY DIGESTED, and admirably adapted for invalids as well as for persons in health.

Sold by Grocers everywhere.

WATERTOWN, SOUTH DAKOTA.

In previous advertisements we have said little of what nature has done in providing Watertown with pleasant and picturesque surroundings; it is, however, a magnificent setting for the two jewels—Lakes Kampeska and Pelican—which the Creator has placed in this prairie crown.

LAKE KAMPESKA is a body of pure spring water, covering an area of eighteen square miles, mostly surrounded by high embankments. A clean, gravelly beach from twenty to thirty feet in width skirts the entire lake, except where broken in a few places by large boulders extending to the water's edge. It is fed by numerous large springs, insuring a continuous and inexhaustible supply of

THE PUREST DRINKING WATER IN THE WORLD.

The bottom, like the shores, is of sand and gravel, the water clear and cool. Fish abound in great quantities, affording plenty of sport for those who enjoy angling. Situated three and one-half miles west of Watertown, it is the source of water supply, and thus is Watertown doubly fortunate, having so lovely a pleasure resort at her very door, and such an inexhaustible supply of pure water for domestic purposes. Being connected with the city by a motor line, safe and rapid transit is afforded.

VIEW ON LAKE KAMPESKA, NEAR WATERTOWN — LAKEVIEW PIER AND STEAMER.

LAKE PELICAN is about one-half the size of Kampeska, and is situated but one and one-half miles from the city. The water is not so deep nor are the shores as pebbly as those of the former lake. In winter, Lake Pelican affords rare opportunities for ice-boating, though the success of this sport depends somewhat upon the fall of snow.

The attractions of these two bodies of water are features of which no other city in South Dakota can boast.

WINTER SPORTS—ICE-BOATING ON LAKE PELICAN, NEAR WATERTOWN.

In a future issue we shall speak particularly of the unparalleled advantages of Watertown as a manufacturing site and give, from official sources, statistics of the comparative profit of manufacturing in the East and West.

LADY AGENTS WANTED.

I have a medical specialty for ladies use, which is one of the best selling articles in the country. You can make a good income handling it, and at the same time be doing your sex a great benefit. Write me at once for full information and exclusive territory. If you wish a sample sent enclose 12 cents postage. Dr. H. H. Jackson, 103 State Street, Chicago.

We can save you Fifty Dollars when you Build. See

A complete set of Plans to build from, simply state about price of dwelling desired. 25 cts. in stamps. Our book "Beautiful Homes." 25 cts. Our monthly book "The National Builder," 25 cts. Address

The National Builder, Adams Exp. Bldg., Chicago, Ill.

THE QUEEN'S PRIZE SCHOOL OF HISTORY.

About two years ago the publishers of THE CANADIAN QUEEN added what has proven to be a very popular and successful feature to their publication in establishing their Prize History School. It has offered competitive examinations in English, Canadian and American History, giving valuable rewards to those making the most correct answers. During this time there have been added the names of over forty thousand new subscribers to their books. Rewards have been made by THE QUEEN which have cost them in cash over ten thousand dollars. THE QUEEN'S Prize School of History has received the sanction and support of the clergy, press, and, in fact, of the best people of the Dominion of Canada. The following, taken from a leading daily newspaper, expresses an opinion which is universal:

A HANDSOME PRIZE.

AN EVIDENCE OF WHAT A GENUINE MAGAZINE COMPETITION OFFERS.

"On Friday there arrived from Toronto, for Miss M. Hora, a handsome Shetland pony, harness and cart, being the first award in the Royal Quilt Competition of THE CANADIAN QUEEN magazine. It attests the genuine nature of the magazine's contests by its excellent condition and value. THE QUEEN has frequent competitions and has made innumerable awards, displaying a generosity quite surprising to those who have had experience of the limited field for Canadian journalistic enterprise. But THE QUEEN has been a success as a business venture from the start, and is growing in literary excellence steadily. It covers the field of fashion, as well as light reading; talks to the household, the young, and, indeed, all home classes. The competitions have been used to assist the introduction of the magazine, for where it is introduced it is quite certain to remain a monthly guest. The leading prizes have been made, as instance this latest to Kingston, while many smaller prizes have rewarded the moderately successful among competitors. THE CANADIAN QUEEN is truly royal in its ways."—*The (Kingston, Ont.) Daily British Whig*, June 27th, 1891.

QUESTIONS IN AMERICAN HISTORY.

1.—Give the names of the early navigators who it is claimed by historians first discovered America.
2.—From whom has America taken its name?
3.—What class and nationality first settled Virginia? New York? Massachusetts? Pennsylvania? Maryland?
4.—What action did the Continental Congress of 1774 take and what was the result of that action?
5.—What was the first battle fought in the War of the Revolution?
6.—What nation rendered the Americans great assistance in the War of the Revolution?
7.—Give the names of the committee appointed to draft the famous Declaration of Independence.
8.—What was the date of the signing of the United States Constitution?
9.—After becoming a nation and before the great Civil War, what were the principal conflicts which engaged the Americans?
10.—What was the direct cause of the Civil War? What Generals of the Northern Army have occupied executive positions under the Federal Government since the closing of the War? Who was Commander-in-Chief and who were the principal Generals of the Confederate Army during the struggle?
11.—How long did this War last and what is the computed loss of life?
12.—What can be said to day of the United States as a nation?

To the *First* gentleman sending the correct answers to the above questions in American History the publishers of THE QUEEN will present "**Majestic**" acknowledged the **Handsomest and Finest Riding Horse in Ontario.** ("Majestic" is sixteen hands high, thoroughbred, seven years old, and valued at $350.00.) To the *First* lady the publishers of THE QUEEN will present an elegant **Jacket of Genuine Alaska Seal** to be made according to the measurement supplied by the winner. To the *First* boy under sixteen years of age the publishers of THE QUEEN will present a **Little Giant Safety Bicycle** valued at $75.00. To the *First* girl under sixteen years of age the publishers of THE QUEEN will present an elegant **Music Box,** playing twenty tunes, finely finished and valued at $55.00.

To the gentleman from whom the *Last* correct answers are received before the close of this Competition, the publishers of THE QUEEN will present a **First Cabin Passage to Europe and Return** and **$200 in Gold** for expenses. This trip can be taken by the winner any time before October 1st, 1892. To the lady from whom the *Last* correct answers are received before the close of this Competition the publishers of THE QUEEN will present a **Pony, Cart and Harness.** To the boy under sixteen years of age from whom the *Last* correct answers are received before the close of this Competition the publishers of THE QUEEN will present a **Solid Gold Watch** containing one of the best American movements, and valued at $75.00. To the girl under sixteen years of age from whom the *Last* correct answers are received before the close of this Competition the publishers of THE QUEEN will present an elegant **Solid Gold Watch,** containing one of the best American movements, and valued at $65.00.

ADDITIONAL PRIZES IN ORDER OF MERIT: Silver Tea Services, Ladies' Gold Watches, Silk Dress Patterns, French Mantel Clocks, Portiere Curtains, Toilet Cases, Manicure Sets, and many other useful and valuable articles.

The object of the publishers in offering these liberal prizes is to introduce THE QUEEN Magazine into **new** homes. Answers must be mailed *on or before* November 10th, 1891, and must be accompanied by $1.00 for one year's subscription to THE CANADIAN QUEEN. Prizes awarded to subscribers residing in the United States will be shipped to them **free of duty.** The distribution of awards is in the hands of disinterested persons, and decisions will be based on the correctness of answers. Use your own language in wording the answers. No corrections can be made after your answers are mailed. THE QUEEN is a large, forty-eight page family magazine, especially interesting to ladies and children, and visits regularly **over one hundred thousand of the best homes** in Canada and the United States. The awards in THE QUEEN'S Prize School of History are made strictly with regard to merit, without partiality to persons or locality. The decisions must be accepted as final. If you have never seen a copy of THE QUEEN send six U. S. two cent stamps and receive a late number, post paid, containing letters from those who have received rewards in previous contests.

Address THE CANADIAN QUEEN, PRIZE SCHOOL OF HISTORY, 58 BAY STREET, TORONTO, CANADA.

TABASCO PEPPER SAUCE,

OR LIQUID PEPPER.

Is simply the Pulp of the Ripe Pepper Extracted by Pressure.

The seed of this Pepper was obtained from Central America, and by careful cultivation in Louisiana for many years has been so improved in strength, flavor and aroma, as to have become a new variety of Red Pepper, superior to all others. The pulp is so handled as to retain all the flavor, strength, aroma and color of the ripe fruit, and to keep unimpaired in any climate. It excites the appetite, promotes digestion, and is pronounced by connoisseurs to be the finest condiment in the world. For medicinal purposes it recommends itself by its purity, strength and diffusible form.

Manufactured by E. McILHENNY'S SON,

NEW IBERIA, LA.

For Sale by all Wholesale Grocers.

GOITRE, or THICK NECK.

I have a positive, speedy, cleanly, harmless and almost inexpensive cure. Come or write to me at 28 Arlington Court, CLEVELAND, Ohio. It is no iodine smear. Cure made permanent.

Dr. J. CASKEY.

NATRONA BI-CARBONATE OF SODA.

ABSOLUTELY PURE.

The nature of the raw material from which NATRONA BI-CARBONATE OF SODA is made—viz., kryolith, a mineral containing *pure sodium*—insures a purity and uniformity of product which cannot be obtained from any other known material. In making BI-CARB. SODA from any other raw material, the use of sulphuric acid is a necessity, but none is used in any part of the process of making NATRONA BI-CARB.; hence its entire freedom from the slightest trace of arsenic, which is always present in ordinary soda. Its absolute purity and entire freedom from all traces of *sulphate of soda*, common salt and other impurities, render NATRONA BI-CARB. NEARLY TASTELESS, and being bolted through the finest bolting-cloth, insures the finest stage of division.

To these indisputable facts the attention of CONSUMERS of soda is specially called. They are IMPORTANT, and should influence both those who use and those who sell soda, to buy and sell NONE BUT THE BEST.

The NATRONA BI-CARB. Soda is kept in stock by almost every wholesale druggist and grocer throughout the United States, of whom it may be ordered.

Natrona Bi-Carb. Soda is unequaled by any other brand of English or American Manufacture.

DO YOU KNOW THE **DANGER** OF USING SOAP?

IF YOU ARE GOING TO THE COUNTRY, DO NOT FAIL TO READ THE FOLLOWING.

WE do not mean soap made from proper material; and when we tell you that about ninety-nine per cent. of Toilet Soap is made from refuse fats gathered from tenement houses, hospitals, butcher shops, and from cattle dying of disease or during transportation, you will, we believe stop and think. Putrefactive changes have taken place in most of this material, as it is mixed with lean meat, blood, bones, sinews, etc. There is at least *one* soap that is made wholly from vegetable material—OLIVE and PALM OILS—and that is

VELVET SKIN SOAP.

It will keep the skin soft and in a healthy condition, as no animal fats are used in its manufacture.

Nothing in one's personal outfit is quite so satisfactory as a thoroughly reliable Toilet Soap.

We are confident that a trial of this article will insure its continued use. If the dealer does not keep it, do not take any other, but require him to order it for you, which he can do readily. **Otherwise, send to us direct.**

FOOD MANUFACTURERS' ASSOCIATION.

We have received a copy of the constitution and by-laws of the Food Manufacturers' Association of this city, and as the AMERICAN ANALYST, ever since its establishment seven years ago, has steadfastly maintained that pure food could and would drive out impure and adulterated food products, we look upon the project with considerable pride, and hope to see it crystalize into a permanent, strong and healthy movement in the right direction. It does not matter who organized this particular association, the grand idea was established and the original stimulus imparted to it by this journal. It is natural, therefore, that we should watch its growth with interest, and keep an outlook to see that it receives no harm from those who may succeed in identifying themselves with it from purely selfish motives. The statement in the preamble, of the objects of the association, seems to be a fair presentment of what it should be, and if those purposes are carried out as promised, they must result in great benefit to the honest manufacturer and in still greater benefit to the consumer. There are undoubtedly many difficulties in the way which will have to be overcome. We have already pointed out one of them. Another source of danger which we look upon with considerable apprehension is the presence in the management of at least two firms whose products can by no means be classed in the category of pure wholesome food. Is not their presence in that body a menace to the association? Is it due to a desire to so pull the wires as to give the impression to the public that their products also are pure and wholesome? Do they depend upon this kind of a bold bluff in the way of a reassuring inference by the public that if they knew their wares to be impure they would not dare to take the bold stand they apparently do for pure food? Will their presence in the board of management serve to keep out other manufacturers of concededly pure food products, who will not care to place pure unadulterated goods alongside of those known to be impure and adulterated. These are vital questions that cannot be ignored. A further source of danger is in the fact that while in some cases it is almost impossible for any one to draw a sharp clearly defined line between pure and impure goods, it must be especially difficult if manufacturers of impure goods have any voice in the settlement of the question. The object of enlightening and educating the public as to what really is wholesome, and of the desirability of using the best quality of food, is the most important of all. Whether this can be done by means of food exhibitions alone to any appreciable degree is very doubtful, because an exhibit of impure food can be made to look equally, if not more, attractive than the purest product, as we had occasion to demonstrate practically at the lamentable grocers' fair at the Lenox Lyceum last winter. Allowing the public to taste samples of foods may show what the public taste likes or dislikes, but it neither proves nor disproves anything as to purity. We have reason to believe that the officers of this association mean to do what is fair and honorable, and to carry out the true spirit of their undertaking. We shall closely watch every step that we may be able, as occasion offers, to point out to our readers every favorable advance made. We shall be just as quick to detect any attempt to humbug or throw sand in the public eye, but we sincerely hope that so commendable a movement will not be marred by any such disgraceful work. The honest food producers, who constitute the majority in the new organization, cannot afford to allow any selfish minority to make the tail wag the dog. We reproduce below the preamble to which we have referred, in order that our readers may appreciate the standard by which they are asked to measure the future actions of the association:

The objects of the Food Manufacturers' Association are to promote the manufacture, sale and consumption of wholesome food products, and to establish close and cordial relations between the manufacturer, distributor and consumer. To foster a friendly feeling between the various food manufacturers, and to gather and disseminate knowledge for their mutual benefit. To endeavor by every legitimate means to improve the quality of food, and to elevate and maintain a general standard of purity, wholesomeness and quality. To enlighten and educate the public by means of food expositions as to what really is wholesome, and of the importance of using the best quality of food.

FASHION AND BACTERIA.

According to the *Extra Blatt*, of Vienna, the police bureau of that city has recently issued a circular that strikes a heavy blow at the liberty of women. The fair Austrians have already protested against the circular; their foreign sisters, it is believed, will aid them in the crusade against its execution. "The high imperial and royal government," reads the circular, according to the papers, "has under consideration the question of the advisability of denying women the privilege of wearing trains to their dresses on the public streets. The federal sanitary council of Lower Austria has expressed the opinion that the wearing of such trains should be forbidden, as they raise the dust and thus aid in conveying the germs of infectious disease to the lungs. The practical execution of a measure forbidding the use of such trains, however, is coupled with many difficulties, as are all measures dealing with excesses in style. In accordance with the wishes of the imperial and royal government, the commissioners of police are requested to present their views upon the necessity and availability of such a measure." The *Extra Blatt* fails to inform us of the reports of the medico-Worths of the Viennese police. This is a matter that New York would do well to heed also. Any observant person walking in the vicinity of the large retail stores of this city during the afternoon hours, when the feminine "shopping" element is abroad in force, will speedily be convinced of the risk to health that must attend the street-sweeping scavenger work performed by the absurd long-trained dresses now in vogue. But when do mere considerations of health or hygiene regulate the fashion?

HONEST OLEO.

From the outset of the oleomargarine contest the AMERICAN ANALYST has steadfastly maintained the opinion that that commodity would ultimately vindicate itself as a cheap and wholesome substitute for butter, far preferable to a great mass of the vile stuff that is sold under that latter name. From a Washington despatch of September 14th, we are assured that the figures of the Internal Revenue Department, in regard to this year's product of oleomargarine, are going to surprise the dairymen throughout the country and others interested in the manufacture of artificial butter. Last year the receipts from the tax on oleomargarine were $786,291, as against $894,247 for the preceding year, a decrease of $107,000. This year there will be shown an increase of fully forty per cent.,

something wholly unexpected. The theory held by the officers of the bureau is that oleomargarine is steadily winning its way in public favor as an article of commerce put upon the market simply for what it is. They believe that people generally are beginning to recognize it as a cheap and healthful substitute for butter. It is noticeable from the returns that more oleomargarine is sold in the mining regions, distant from the markets, than anywhere else. This is because it "keeps," and does not become rancid as time goes by. Heretofore the output of oleomargarine has depended in a very great measure upon the grass crops. When these crops were good, and the cows consequently gave milk freely, the Government receipts on account of the tax upon oleomargarine, amounted to almost nothing. When the grass did not grow well, then there came a demand for oleomargarine. The unprecedented figures showing this year's increase from the tax on oleomargarine, would induce the belief that it has come to stay, grass or no grass.

ELECTRICITY AND LIFE.

IS ELECTRICITY SOMETHING MORE THAN A STIMULATING FORCE?

It seems to be a pretty well established fact that electricity may be made at least a powerful stimulant to the growth of plants. May it not be more than a mere stimulant? May it not be an actual creator of life? Beans, rye, corn, oats, barley, peas, potatoes, sunflowers, clover and flax, have all been experimented upon, in some cases with astonishing results. In one series of experiments the seeds were electrified before they were sown; in another, currents were maintained through the soil in which they were planted; and still another, through the atmosphere immediately above the plants. In several instances the yield of fruit was enormously above the average, and in all the growth was unusually luxuriant. Further experiments are in progress, and it is not unlikely that science is about to add another to her long series of beneficent triumphs, another refutation to the croaking philosophy of Malthus and his disciples. The results of the experiments have, furthermore, a suggestive bearing upon the relation between electricity and that inscrutable something which we call life. If they do not prove them the same, they at least bring them nearer together than any phenomena which have preceded them. When, in the healing art, enfeebled vitality is restored, either wholly or in part, by the skillful application of electricity, nothing is positively demonstrated beyond mere healthful stimulation, the mere awakening of life which already lay dormant in the system, such as might possibly have followed the use of other remedial agents But here it is not morbid restored to normal conditions, not dormant life reawakened to action. It is apparently the actual development of vitality not pre-existent in the perfectly healthy and normal organisms under treatment. Electricity itself, appears to be converted to vitality, as elsewhere it is converted to light, heat and mechanical motion. Whether life can thus not only be renewed, but actually transfused into the veins, or rather, the nerves of man, remains for physiological science to determine. It has already been shown that a living body is a species of thermo-electric battery, of which the ectoderm and the endoderm are the opposite poles; that the exhilarating effects of a cold plunge, for example, are due simply to the increase of potential from the reduced temperature of the "cold" electrode. But merely setting a battery into operation, or merely increasing its action, is not increasing its inherent voltage, which is what the recent experiments seem to have done for plants. But do not heat and the active principle of light artificially intensified produce similar effects? The forcing of vegetable growth in hot-houses is an old process and unlike the one in question, both in method and effect. According to the reports given, however, there is a very great difference in the results attained. If this be true, it would seem to indicate more strongly than ever that of all forms of natural force, electricity bears the closest relation to that mysterious form of it which we call life.—*N. A. Review.*

TELESCOPES.

THE HISTORY OF THEIR EARLY DEVELOPMENT.

Professor C. S. Hastins in a paper published by the *Siderial Messenger* of Northfield, Minn., says: Galileo learned in 1609 while visiting Venice, that a marvelous instrument had been invented the preceding year in Holland, which would enable an observer to see a distant object with the same distinctness as if it were only at a small fraction of its real distance. It required but little time for the greatest physicist of his age to master the problem thus suggested to his mind, and after he returned to Padua where he held the position of professor of mathematics in the famous university of that city, he set himself earnestly to work making telescopes. Such was his success that in August of the same year he sent to the Venetian Senate a more perfect instrument than they had been able to procure from Holland, and in January of the next year, by means of a telescope magnifying thirty times, he discovered the four satellites of Jupiter. This brilliant discovery was followed by that of the mountains of the moon; of the variable phases of Venus, which established the Copernican theory of the solar system as incontestable; and of the true nature of the milky way together with many others of less philosophical importance. Galileo did not change the character of the telescope as it was known to its discoverer in Holland, but he made it more perfect, and was the first to apply it to increase the bounds of human knowledge. Considering the enormous interest excited throughout intellectual Europe by the invention of the telescope, it seems surprising that its early history is so confused. Less than two years after it was first heard of, a discovery, perhaps the greatest in a thousand years in the domain of natural philosophy had been made by its means. Nevertheless, the three contemporary, or nearly contemporary, investigators assign the honor to three different persons. It seems to be well established now, however, that Franz Lippershey or Lippersheim, a spectacle maker at Middleburg was the real inventor of the telescope, and that Galileo's first telescope, avowedly suggested by news of the Hollander's achievement, was an independent invention, but based upon somewhat precise information, such as that the instrument consisted essentially of two lenses, of which one was a magnifying and the other a diminishing lens. That the discovery was really an accident we may be quite sure, for not only was there no developed theory of optics at the time, but even the law of refraction which lies at the basis of such theory was quite unknown. After Galileo had proved the existence of spots on the sun in 1611 no other discoveries of moment were made until over a generation. By the middle of the 17th century, however, several makers of lenses had so far improved the methods of grinding and polishing, that telescopes notably superior to that of Galileo were procurable. Among the makers were Auzont, who constructed a telescope 600 feet long (but no means was ever found for directing such an enormous telescope toward the heavens), and Huyghens, who won distinction for his discovery of the nature of Saturn's rings, with a telescope of his own invention. A few years later, the famous astronomer Cassini having come to Paris from Italy as Royal Astronomer commenced a series of brilliant discoveries with telescopes, which varied from 35 to 136 ft. long, made by Campani of Rome. Cassini's discovery of the third and fourth satellites of Saturn marks the furthest reach of the old form of telescope; a century was to elapse and an entirely new form of telescope was to be developed before any considerable addition was to be made to the stock of our knowledge of the aspect of the heavenly bodies. The older opticians had found that if they attempted to increase the diameter of a telescope they had to increase its length in a much more rapid ratio to secure distinct vision. Newton found the cause in what is now known as chromatic aberration, and convinced that this obstacle to further improvement in the refracting telescope was insuperable, he turned his attention to the construction of a reflecting telescope, and made one which had about the same power as Galileo's although little over six inches long. Even after Newton's invention was made public, little was done for the improvement of telescopes for half a century until Hadley presented a reflector of his own construction to the Royal Society, in 1723, which was found to be equal to the Huyghens refractor of 123 feet in length. A few years later Short commenced his career as a practical optician, and for thirty years he was unapproached in the excellence of his instruments; but telescopes were costly and discoveries unimportant. In 1766, a new star rose on the astronomical horizon in the person of William Herschel, the German organist of Octagon Chapel, Bath. He became profoundly interested in telescopy, and finding the cost of a satisfactory telescope beyond his means he determined to construct one for himself. Fortunately for science as well as for himself, he made, early in his career, a discovery of the very first importance, which attracted the attention of all Christendom. This was the discovery of Uranus, which led to his appointment as astronomer to the King, George III., with a salary sufficient to admit of his devoting his whole time to astronomy. We must go back now to a quarter of a century before Herschel discovered the new planet to notice another form of telescope which has remained unrivaled for the last half century in the more difficult fields of astronomical research. This is the achromatic telescope invented by Dolland. For a long time this ingenious invention remained fruitless for astronomical discovery on account of the difficulty of securing sufficiently large and perfect pieces of glass, more particularly of flint glass. This difficulty was finally solved by the Swiss watchmaker Gorinand, in concert with Frauenhofer, the optician, and they and their successors have so carefully preserved the secret of their success that all the large pieces of optical glass which have since been produced have been made by Gorinand's direct heirs. For a long time, Frauenhofer and his successors, Marz and Mahler, from whom the great telescopes of Pulkorva and of the Harvard Observatory were procured, remained unrivaled in this field of optics, but they have been followed by a number of skillful constructors in this country and in Europe whose products have, since the middle of the century, been scattered over the world.

CHARACTER IN NAMES.

THE SIGNIFICANCE OF NAMES IN NOVELS.

I suppose all novelists and story-tellers take some proper godfatherly or godmotherly care in the christening of their creatures. If they go no deeper, they at least observe the more superficial and obvious distinctions between character of bourgeois and gentle blood. They seek names appropriate to calling or locality, and so forth. Most take some pains about the naming of hero and heroine. One class of novelists appeals to a sentiment of romance, with high-sounding, historic names; another betrays the inevitable significance of nomenclature by scrupulously employing none but the most familiar. Nothing short of democratic training and Bostonian naturalism could have hardened Mr. Howell's heart into inflicting upon his Lady of the Arostook and her many admirers, for the sake of whatever dramatic point, the revolting surname Blood. Beautiful and picturesque names are no small element in the picturesque beauty of romance. Generations of

hearts have beaten time to the syllables Wilfred of Ivanhoe or Lucy of Lammermoor. The degradation of name is a bit brutal, even for parody, in the diverting "Rejected Address" which transforms—

"Charge, Chester, charge! On, Stanley, on!"
Were the last words of Marmion,

into

"'Od rot 'em,"
Were the last words of Higginbottom.

Thanks to what Matthew Arnold termed the touch of grossness in our race, we are bountifully provided with names of all shades of vulgarity and hideousness. With us no booby or villain, at all events, need go inappropriately named. It is unpardonable in fiction, however, to burden a charming girl with a vile name, and to make heroes of Higginbottoms is a mere wantonness of Zolaism. Art exists to console us for the hardships and anomalies of life. In the world of art there should be some subtle appropriateness in the naming of the *dramatis personæ*. What should be the nature of the appropriateness? What should be the secret of the affinity? Should novelists permit themselves to manufacture names with an obvious meaning, like Fielding's *Alworthy* for instance? Or, like Balzac, should they search for mystic meanings in real names? Can there possibly be any affinity, apart from the special associations of a book, between a mere meaningless proper name and a character? Chadband, Miss Miggs, Micawber, Pecksniff, Sairy Gam—were these names once absolutely non-significant? Surely, in the mere name of Micawber, there already lurk suggestions of a waiting for something to turn up. Enthusiasts have been known to protest that from Silas Wegg's bare name they divined the whole man, wooden leg and all. Not a bit of it, retorts rationalizing commonsense; make the experiment in a properly scientific spirit and see. Get a man innocent of Dickens to evolve from the letters of the word Pecksniff the character of the Salisbury architect, or from the data of a misshapen body and sly domestic cruelty, ask him to construct the name Quilp. Well, and suppose he fail, his failure is by no means fatal to the theory. Nature undoubtedly affords abundant instances of mysterious affinities between apparently heterogeneous things. Scents, sounds, and colors have infinite capacities of spiritual suggestion. Herein lies the secret of the potency of the sensuous arts. What analysis could exhaust the possible suggestiveness of names? There are forebodings in the mere sound of the syllables, and mysterious intimations in the mere look of the letters, which baffle all attempts at rational explanation. On this groundwork association has woven threads of suggestions, philological, historical, romantic. It is true that it is only after name and character have been joined together by the inspiration of the author that they cannot again be put assunder; but the marriage only reveals, and does not beget, the elective affinity. According as the element of allegory or the element of realism predominates in the artist's method, will be the wisdom or unwisdom of employing realistic or allegorical names. Where allegory predominates, as in "The Pilgrim's Progress," where our attention is directed, as in the motley crowd who people the English comic stage, chiefly to the skill of the dramatist in showing up the foibles of humanity, and winding mean and vicious actions into situations of laughable entanglement, then names which point the character and explain situations come naturally in place. Where, however, it is sought to stir pity and fear and sympathy with the sufferings and heroisms of men and women; where, as in tragedy, self-conscious observation of the writer's art should be lost in overwhelming feeling for the hero's destiny, then, so far I know, such names have never been adopted. Of names of this kind Shakespeare is sparing in the use. Justice Shallow, Slender, and Silence, with Fang and Snare, the Sheriff's officers—the majesty of the law always fares badly in the hands of satire; the constable, Dull; Froth, a foolish gentleman; Martext, a vicar; and that ragged regiment of Falstaff's recruits, Mouldy, Shadow, Wart, Feeble, and Bullcalf—these almost exhaust the list. It is not difficult to see with how much natural ease Dickens can introduce his Jingles and Veneerings. The art of Dickens is often the art of caricature, often it is the art of farce. His world is a grotesque, pathetic, lurid, ludicrous world of his own. He has brought together a teeming population of quacks and mountebanks, and waifs and strays, and monstrosities, for whom his most extravagant names are accepted as the only natural and proper ones. What shall we say, however, of Thackeray and his Deuceaces and Bareacres and the rest? His justification, if it be right to speak of justification, lies in this; that with all the solid reality of the life portrayed, we are never allowed to lose sight of the author and his art in portrai ure. He is ever at hand to underline the snobbery or laugh off the pathos. He is especially fond of putting on the airs and graces of the showman. His preface to "Vanity Fair" is headed, "Before the Curtain;" and this great novel of real life concludes with "Come, children, let us shut up the box and the puppets, for our play is played out.—*Edinburgh Magazine.*

IMITATION PERFUMES.

HOW CHEMISTRY CAN PRODUCE THE FRAGRANCE OF FRUIT AND OTHER ODORS.

Chemistry has found it possible not only to analyze perfumes, that is the ottos or essential oils, that would seem their final resting place, but to build up substances that have similar odors. Rum-ether, the substance to which rum owes its perfume, whose chemical name is too troublesome to give, is a regular article of commerce in Austria. It is made by taking 12 pounds each of sulphuric acid and black oxide of manganese, 26 pounds of alcohol and 10 of strong acetic acid. These ingredients are mixed and 12 pints distilled from them. Butyrate of pure ethyloxide possesses a delicate odor of pineapple, which by the addition of wine or potato spirits, may be altered to that of strawberry and raspberry. Nitric ether, 50 grammes; acetate of amyl and glycerine, 100 grammes each, with one litre of purest alcohol, will imitate the odor of pears, and more complicated compounds imitate the apple set. These are not like the perfumers' imitations—apt combinations of substances whose composition is unknown to him, but absolute buildings up of those subtlest of all things, odors from substances every one of which the chemist can control and make out of other known substances till the ultimate known elements are reached.

TABLE NONSENSE.—It is authoritatively announced that the employment of a piece of bread for assisting the fork in securing a savory morsel is now tabooed, and that he who thus pursues a slippery titbit around a slippery plate is no better than the man who eats peas with the aid of a spoon or cuts lettuce with a knife. Little by little, the satisfying of the appetite is turned into a feat of legerdemain, and the obtaining of food is now not so difficult a task as the enjoyment of it according to the rules of etiquette. Pleasure is thus mingled with anxiety. The bashful man often denies himself; and he envies the dog that secures his bone and, careless of remark, devours it naturally.—*Hotel Mail.*

COSTLY LIVING.—In Chile everything is wonderfully expensive but muscle, and that is of comparatively little value. A lady's bonnet costs from thirty to one hundred dollars; dress silk from six to twenty dollars the yard, and the modiste will charge you from thirty to fifty for making it. In Santiago, I paid twelve dollars the dozen for linen handkerchiefs, small size and ordinary quality, and eighteen dollars for a pair of button boots which at home would have cost about $4.50. I am informed that a gentleman's suit of common clothes cost from sixty to a hundred dollars; a pair of patent-leather shoes from $15 to $30; and a silk hat not less than $25. Breadstuffs are correspondingly high, and far beyond the reach of the poor rotos. —*Corr. Bost. Transcript.*

UNSEASONABLE HAPPINESS.—A new waitress in a certain family astonished the members thereof by bursting into song the first time that she waited upon them at dinner. When her mistress spoke to her about it she said, "Why, was I singing? Well, I often do when I feel happy."—*Boston Transcript.*

RAIN COERCER.—In all this talk about rain-making agencies, we are surprised at the way in which sunday-school picnics are ignored. An able-bodied sunday-school picnic in a nice grove about five miles from any shelter will bring rain quicker than any contraption that General Dryforthwith can invent. Not his name? Oh, well, it is near enough to go.—*Tribune.*

SMOKE SCREEN.—Through experiments made by English military authorities it has been found that whenever the atmosphere is laden with smoke or mist the power of an electric light is greatly diminished by crossing the beam of light by that of another at a certain angle. At the point of intersection the illuminated space is practically made a screen. It is proposed to utilize this knowledge, since the electric beam can thus be made to serve as a screen, back of which tactical operations might be conducted in secret.

DOMESTIC INSURANCE.—"The Integrity Mutual Beneficial Association" is the name of a sociey just organized in Philadelphia. The charter declares that its purpose is to "collect and accumulate a fund by admission fees, monthly dues and assessments, in order to benefit and aid its members in the event of their marriage, and to benefit its members upon their surviving a period of years, and to benefit and aid the widows and widowers and children of deceased members, and for the furtherance of the general welfare of the members thereof."

FIREPROOF PROCESS.—Still another process for fireproofing combustible materials is reported from Russia, the medium being described as paste, which is said to have been tested recently with most satisfactory results by the Moscow Imperial Society. A shanty was built entirely of straw, and, after being covered with the paste, was subjected to a hot fire, the only effect being to change the straw from a yellow to a reddish-brown color, without igniting or even cracking. The society referred to has consequently made arrangements, it is said, to introduce the use of this new invention throughout the empire, considering it from every point of view as of the highest value in villages or localities where the houses are, as a rule, thatched with straw, and where fires, once started, frequently make a clean sweep of the place. The cost of the preparation is very small.

ARTIFICIAL DYES.—Few instances of modern industrial growth in any one specialty are more surprising than that of the manufacture of artificial dyestuffs. In England, France, Germany, and some other countries, but especially in Germany, this industry has attained such prodigious growth that in some cases the extensive works resemble a small town or village. This appears from the published statistics of one of these plants—that of the Farbwerke, at Hoechst-on-Nain, where are employed some 1,900 workmen, 50 foremen, 9 engineers, besides 86 clerks and 57 chemists. The works cover an area of 726,000 square yards, and from one end of the works to the other the distance is 3,300 feet. Besides a great variety of dyestuffs, the acids employed in their production are also manufactured, amounting in one year to 23,108,000 kilograms of sulphuric acid, 12,800,000 of other acids, and 3,624,000 of coal tar products.

THE MOON'S SHAPE.—Referring to the fact that the photographs of the moon, taken at full, give that body an egg-shaped appearance, with the small end pointing toward the earth, a recent writer argues that this goes to prove that planet's non-globular shape, as was indeed to be expected. According to this writer's reasoning, matter at the surface of the moon is acted upon by two important forces—the law of gravity would arrange the matter in a globe around the centre, the moon alone considered, and the attraction of the earth, being always exerted in the same direction relative to the moon's centre, would constantly draw all fluid or plastic matter to the side next the earth; the sun shines not less than 325 hours consecutively on any given point on the moon's surface, and it is not probable that water on the surface would remain frozen under such continued sunshine, so that doubtless the fluid part of the moon's surface, obeying the constantly acting force that generates the tides on the earth, have long since gathered themselves together on that side of the moon nearest the earth. This idea, it is claimed, is not inconsistent with anything developed by the shadow of the moon in eclipses, not with any known fact.

BRIGHT STORIES.

THE SNOWSTORM.

From the Russian of Alexander Pushkin.

(Concluded from page 449.)

Meanwhile, the war had been brought to a glorious conclusion, and our armies were returning from abroad. The people ran to meet them. The music played by the regimental bands consisted of war songs, "Vive Henri-Quatre," Tyrolese waltzes and airs from Jaconde. Nourished on the atmosphere of winter, officers who had started on the campaign mere striplings returned grown men and covered with decorations. The soldiers conversed gayly among themselves, mingling German and French words every moment in the speech. A time never to be forgotten—a time of glory and delight! How quickly beat the Russian heart at the words "Native land!" How sweet the tears of meeting! With what unanimity did we combine feelings of national pride with love for the Tsar! And for him, what a moment!

The women—our Russian women—were splendid then. Their usual coldness disappeared. Their delight was really intoxicating when, meeting the conquerors, they cried "Hurrah!" and they threw up their caps in the air.

Who of the officers of that period does not own that to Russian women he was indebted for his best and most valued reward? During this brilliant period Maria was living with her mother in retirement, and neither of them saw how, in both capitals, the returning troops were welcomed. But in the districts and villages the general enthusiasm was, perhaps, even greater.

In these places the appearance of an officer became for him a veritable triumph. The accepted lover in plain clothes fared badly by his side.

We have already said that, in spite of her coldness, Maria was still, as before, surrounded by suitors. But all had to fall in the rear when there arrived at his castle the wounded young captain of Hussars—Bourmin by name—with the order of St. George in his button-hole, and an interesting pallor on his face. He was about 26. He had come on leave to his estates, which were close to Maria's villa. Maria paid him such attention as none of the others received. In his presence her habitual gloom disappeared. It could not be said that she flirted with him. But a poet, observing her behavior, might have asked, "S'amor non e, che dunque?"

Bourmin was really a very agreeable young man. He possessed just the kind of sense that pleased women; a sense of what is suitable and becoming. He had no affectation, and was carelessly satirical. His manner toward Maria was simple and easy. He seemed to be of a quiet and modest disposition; but rumor said that he had at one time been terribly wild. This, however, did not harm him in the opinion of Maria, who—like all young ladies—excused with pleasure vagaries which were the result of impulsiveness and daring.

But above all—more than his love-making, more than his pleasant talk, more than his interesting pallor, more even than his bandaged arm—the silence of the young Hussar excited her curiosity and her imagination. She could not help confessing to herself that he pleased her very much. Probably he too, with his acuteness and his experience, had seen that he interested her. How was it, then, that up to this moment she had not seen him at her feet; had not received from him any declaration whatever? And wherefore did she not encourage him with more attention, and according to circumstances, even with tenderness? Had she a secret of her own which would account for her behavior?

At last, Bourmin fell into such deep meditation, and his black eyes rested with such fire upon Maria, that the decisive moment seemed very near. The neighbors spoke of the marriage as an accomplished fact, and kind Praskovia rejoiced that her daughter had at last found for herself a worthy mate.

The lady was sitting alone once in the drawing room, laying out grande-patience, when Bourmin entered the room, and at once inquired for Maria.

"She is in the garden," replied the old lady; "go to her and I will wait for you here." Bourmin went and the old lady made the sign of the cross and thought, "Perhaps the affair will be settled to-day!"

Bourmin found Maria in the ivy-bower beside the pond, with a book in her hands, and wearing a white dress—a veritable heroine of romance. After the first inquiries, Maria purposely let the conversation drop; increasing by these means the mutual embarrassment, from which it was only possible to escape by means of a sudden and positive declaration.

It happens thus: Bourmin, feeling the awkwardness of his position, informed Maria that he had long sought an opportunity of opening his heart to her, and that he begged for a moment's attention. Maria closed the book and lowered her eyes, as a sign that she was listening.

"I love you," said Bourmin, "I love you. I have behaved imprudently, yielding, as I have done, to the seductive pleasure of seeing and hearing you daily." Maria recollected the first letter to St. Preux in "La Neuville Heloise." It is too late now to resist my fate. The remembrance of you, your dear incomparable image, must from to-day be at once the torment and the consolation of my existence. I have now a grave duty to perform, a terrible secret to disclose, which will place between us an insurmountable barrier."

"It has always existed," interrupted Maria; "I could never have been your wife."

"I know," he replied quickly; "I know that you once loved. But death and three years of mourning may have worked some change. Dear, kind Maria, do not try to deprive of me my last consolation; the idea that you might have consented to make me happy if—. Don't speak, for God's sake don't speak—you torture me. Yes, I know, I feel that you could have been mine, but—I am the most miserable of beings—I am already married!"

Maria looked at him in astonishment.

"I am married," continued Bourmin; "I have been married more than three years, and do not know who my wife is, or where she is, or whether I shall ever see her again."

"What are you saying?" exclaimed Maria; "how strange! Pray continue."

"In the beginning of 1812," said Bourmin, "I was hurrying on to Wilna, where my regiment was stationed. Arriving one evening late at a station, I ordered the horses to be got ready quickly, when suddenly a fearful snowstorm broke out. Both station master and drivers advised me wait till it was over. I listened to their advice, but an unaccountable restlessness took possession of me, just as though some one was pushing me on. Meanwhile the snowstorm did not abate. I could bear it no longer, and again ordered the horses and started in the midst of the storm. The driver took it into his head to drive along the river, which would shorten the distance by three miles. The banks were covered with snowdrifts; the driver missed the turning which would have brought us out on the road, and we turned up in an unknown place. The storm never ceased. I could discern a light, and told the driver to make for it. We entered a village, and found that the light proceeded from a wooden church. The church was open. Outside the railing stood several sledges, and people passing in and out through the porch

"'Here! here!' cried several voices. "I told the coachman to drive up."

"Where have you dawdled?" said some one to me. 'The bride has fainted; the priest does not know what to do. We were on the point of going back. Make haste and get out!'

"I got out of the sleigh in silence and stepped into the church, which was dimly lighted with two or three tapers. A girl was sitting in a dark corner on a bench; another girl was rubbing her temples. 'Thank God,' said the latter, 'you have come at last! You have nearly been the death of the young lady.'

"The old priest approached me, saying:

"'Shall I begin?'

"'Begin—begin, reverend father,' I replied, absently.

"The young lady was raised up. I thought her rather pretty. Oh, wild, unpardonable frivolity! I placed myself by her side at the altar. The priest hurried on.

"Three men and the maid supported the bride, and occupied themselves with her alone. We were married!

"'Kiss your wife,' said the priest.

"My wife turned her pale face toward me. I was going to kiss her, when she exclaimed, 'Oh! it is not he—not he!' and fell back insensible.

"The witnesses stared at me. I turned around and left the church without any attempt being made to stop me, threw myself into the sledge and cried 'Away!'

"What!" exclaimed Maria. "And you don't know what became of your unhappy wife?"

"I do not," replied Bourmin; neither do I know the name of the village where I was married, nor that of station from which I started. At that time I thought so little of my wicked joke that, on driving away from the church, I fell asleep, and never woke till early the next morning, after reaching the third station. The servant who was with me died during the campaign, so that I have now no hope of ever discovering the unhappy woman on whom I played such a cruel trick, and who is now so cruelly avenged."

"Great heavens!" cried Maria, seizing his hand. "Then it was you, and you do not recognize me?"

Bourmin turned pale, and threw himself at her feet.

THE QUICK-BOY SAND.

[*The events, which took place on November 23, 186–, are narrated by Reuben Cartwright, Esq., of Bleakirk Hall, Bleakirk-on-Sands, in the North Riding of Yorkshire.*]

A rough, unfrequented bridle-road, rising and dipping toward the coast, with here and there a glimpse of sea beyond the sad-colored moors; straight overhead, a red and wintry sun just struggling to assert itself; to right and left, a stretch of barren down still coated white with hoar-frost.

I had flung the reins upon my horse's neck, and was ambling homeward. Between me and Bleakirk lay seven good miles, and we had come far enough already on the chance of the sun's breaking through; but, as the morning wore on, so our prospect of hunting that day faded further from us. It was now high noon, and I had left the hunt half an hour ago, turned my face toward the coast, and lit a cigar to beguile the way. When a man is twenty-seven, he begins to miss the fun of shivering beside a frozen cover.

The run took a sudden plunge among the spurs of two converging hills. As I began to descend, the first gleam of sunshine burst from the dull heaven and played over the hoar-frost. I looked up and saw, on the slope of the hill to the right, a horseman, also descending.

At first glance, I took him for a brother sportsman who, too, had abandoned hope of a fox. But the second assured me of my mistake. The stranger wore a black suit of antique, clerical cut, a shovel hat and gaiters; his nag was the sorriest of ponies, with a shaggy coat of flaring yellow, and so low in the legs

that the broad flaps of its rider's coat all but trailed on the ground. A queerer turn-out I shall never see again, though I live to be a hundred.

He appeared not to notice me, but pricked leisurely down the slope, and I soon saw that, as our paths ran and at the pace we were going, we should meet at the foot of the descent, which we presently did.

"Ah, indeed!" said the stranger, reining in his pony, as though now for the first time aware of me; "I wish you a very good day, sir. We are well met."

He pulled off his hat with a fantastic politeness. For me, my astonishment grew as I regarded him more closely. A mass of lanky, white hair dropped on either side of a face, pale, pinched, and extraordinarily wrinkled; the clothes that wrapped his diminutive body were threadbare, greasy, and patched in all directions. Fifty years' wear could not have worsened them; and, indeed, from the whole aspect of the man, you might guess him a century old, were it not for the nimbleness of his gestures and his eyes, which were gray, alert, and keen as needles.

I acknowledged his salutation, as he ranged up beside me.

"Will my company, sir, offend you? By your coat I suspect your trade; *venatorem sapit*—hey?"

His voice exactly fitted his eyes. Both were sharp and charged with expression; yet both carried, also, a hint that their owner had lived long in privacy. Somehow they lacked touch.

"I am riding homeward," I answered.

"Hey? Where is that?"

The familiarity lay rather in the words than the manner, and I did not resent it.

"At Bleakirk."

His eyes had wandered for a moment to the road ahead; but now he turned abruptly and looked at me, as I thought, with some suspicion. He seemed about to speak, but restrained himself, fumbled in his waistcoat pocket, and, producing a massive snuff-box, offered me a pinch. On my declining, he helped himself copiously; and then, letting the reins hang loose upon his arm, fell to tapping the box.

"To me this form of the herb *nicotiana* commends itself by its cheapness; the sense is tickled, the purse consenting—like the complaisant husband in Juvenal; you take me? I am well acquainted with Bleakirk-*saper-sabulum*. By the way, how is Squire Cartwright, of the Hall?"

"If," said I, "you mean my father, Angus Cartwright, he is dead these twelve years."

"Hey?" cried the old gentleman, and added after a moment: "Ah, to be sure, time flies—*quo dives Tullus et*—Angus, eh? And yet a hearty man, to all seeming. So you are his son." He took another pinch. "It is very sustaining," he said.

"The snuff?"

"You have construed me, sir. Since I set out, just thirteen hours since, it has been my sole viaticum." As he spoke he put his hand nervously to his forehead and withdrew it.

"Then," thought I, "you must have started in the middle of the night," for it was now little past noon. But looking at his face I saw clearly that it was drawn and pinched with fasting. Whereupon I remembered my flask and sandwich-box, and pulling them out, assured him, with some apology for the offer, that they were at his service. His joy was childish. Again he whipped off his hat, and, clapping it to his heart, swore my conduct did honor to my dead father. "And with Angus Cartwright," said he, "kindness was intuitive. Being a habit, it outran reflection; and his whiskey, sir, was undeniable. Come, I have a fancy. Let us dismount, and, in heroic fashion, spread our feast upon the turf; or, if the hoar-frost deter you, see, here are bowlders, and a running brook to dilute our cups; and, by my life, a foot-bridge, to the rail of which we may tether our steeds."

Indeed, we had come to a hollow in the road, across which a tiny beck, now swollen with the rains, was chattering bravely. Falling in with my companion's humor, I dismounted, and, after his example, hitched my mare's rein over the rail. There was a raciness about the adventure that took my fancy. We chose two bowlders from a heap of lesser stones close beside the beck, and divided the sandwiches, for, though I protested I was not hungry, the old gentleman insisted on our sharing alike. And now, as the liquor warmed his heart and the sunshine smote upon his back, his eyes sparkled, and he launched on a flood of the gayest talk—yet always of a world that I felt was before my time. Indeed, as he rattled on, the feeling that this must be some Rip Van Winkle restored from a thirty years' sleep grew stronger and stronger upon me. He spoke of Bleakirk, and displayed a knowledge of it sufficiently thorough—intimate even; yet of the old friends for whom he inquired many names were unknown to me, many familiar only through their epitaphs in the windy cemetery above the cliff. Of the rest, the pretty girls he named were now grandmothers, the young men long since bent and rheumatic; the youngest well over fifty. This, however, seemed to depress him little. His eyes would sadden for a moment, then laugh again. "Well, well," he said, "wrinkles, bald heads, and the deafness of the tomb—we have our day notwithstanding. Pluck the bloom of it—hey? a commonplace of the poets."

"But, sir," I put in as politely as I might, "you have not yet told me with whom I have the pleasure of lunching."

"Gently, young sir." He waved his hand toward the encircling moors. "We have feasted *more Homerico*, and in Homer, you remember, the host allowed his guest fourteen days before asking that question. Permit me to delay the answer only till I have poured libation on the turf here. Ah! I perceive the whiskey is exhausted; but water shall suffice. May I trouble you—my joints are stiff—to fill your drinking cup from the brook at your feet?"

I took the cup from his hands and stooped over the water. As I did so, he leaped on me like a cat from behind. I felt a hideous blow on the nape of the neck; a jagged flame leaped up; the sunshine turned to blood—then to darkness. With hands spread out, I stumbled blindly forward and fell at full length into the beck.

(*Concluded next week.*)

DOMESTIC DIETETICS.

SPECIALLY PREPARED, FROM PRACTICAL TESTS, FOR THE LADY READERS OF THE "AMERICAN ANALYST."

SEASONABLE FOOD.

September.

GAME AND POULTRY.—Pigeon, chicken, duck, woodcock.

MEATS.—Beef, mutton, lamb, veal, ham, kidneys, liver, venison.

FRUITS.—Apples, bananas, blackberries, gooseberries, huckleberries, grapes, melons, oranges, peaches, pears, pineapple, plums, raspberries, currants.

FISH.—Bass, blackfish, bluefish, clams, cod, crabs, eels, flounders, halibut, herrings, lobster, mackerel, mussels, porgie, prawn, rockfish, salmon, trout, sea-bass, sturgeon, turtle, white fish, whiting.

VEGETABLES.—Beets, beans, cabbage, carrots, cauliflower, corn, cucumbers, egg-plant, garlic, lettuce, onions, parsley, parsnips, potatoes, radishes, rhubarb, savoy, shallots, spinach, squash, tomatoes, turnips.

PRACTICAL RECIPES.

CREOLE POTATO SOUP.—Pare six fine potatoes and put them in the soup pot with a small onion and two stalks of celery cut in small pieces; pour on three pints of boiling water, cover the pot, and cook until the vegetables will easily mash through a seive. After mashing them return the puree to the soup pot and add salt, pepper, a table-spoonful of finely chopped parsley, a teaspoonful of butter, and half a cupful of cream. Boil up, pour into a tureen, and serve.

CURRIED KIDNEYS.—Let the kidneys stand overnight, or for several hours, in cold water in which there is a little vinegar. In the morning take them out of the water and parboil them. Cut them in dice or thin round slices, and add to them a raw potato and a small onion cut in the same shaped pieces; add boiling water enough to just cover them, put a cover over the saucepan and stew gently until the potatoes are tender; season with salt. Mix a teaspoonful of curry powder with a teaspoonful of butter and add it to the stew. Boil up and serve.

PUFFS.—Beat well together a cup of milk, a cup of flour, and a pinch of salt. Beat separately the whites and yolks of three eggs until they are very light; beat the yolks into the flour and milk, and, lastly, add the whites. Pour by spoonfuls into pattypans and bake a light brown. Eat with hard sauce flavored with brandy and nutmeg.

PEACH PRESERVES—Put your peaches into a pot of boiling water and let them stay in it about three minutes, but no longer. Take them out, peel off the skin, and throw them into a pan of very cold water. Take the pits out of a few of the peaches, crack them open, tie them up (shells and kernels together) in a thin cloth, to boil with the syrup. Weigh your fruit, if it is to be preserved whole as it is, then return the peaches to the cold water. If the stones are to be taken out before preserving, cut up the peaches before weighing and then let them stand in a covered dish. Make a syrup, allowing a pound of sugar to each three pounds of fruit, and two cups of water to every three pounds of sugar. Boil and skim, then add the peaches, a few at a time, boil them until clear, then put them into glass jars. When all are cooked let the syrup boil for ten minutes longer, fill up the jars with it, seal, and keep in a cool dark place. These preserves have a rather light syrup. A richer recipe is to skin and cut up the peaches, weigh them, add to them their weight in sugar, and let them stand a couple of hours, then boil down the mass until the peaches are clear; add a few kernels for flavoring. Pour into glasses, seal, and set away.

TONGUE TOAST.—Brown some thin slices of bread nicely on both sides, cut off the crust, butter the slices, and lay them neatly on a hot platter. With a coarse grater grate some boiled tongue over the toast, garnish with parsley, and serve for tea.

CRULLERS.—Rub one cupful of butter into four of flour, until it is quite fine; add a teaspoonful of baking powder, half a teaspoonful of salt, a teaspoonful of cinnamon, a grated nutmeg, and two cups of powdered sugar. Mix these up thoroughly with a knife; add flavoring of vanilla or rose water, and six well beaten eggs. Roll out an inch thick, cut into rings or fancy shapes, and cook a light brown in boiling lard. Turn them with a fork and knife. Take out of the fat with a perforated skimmer and drain for a moment, then dip them in powdered sugar.

SUBSTITUTE FOR LEATHER.—A German inventor has devised a new material which is intended as a substitute for leather in many of its uses. This material consists of panels of wood with wire netting between, the whole being glued together under heavy pressure. The sheets thus made are said to be very tough and pliable, and suited for making trunks, and other uses that require strength.

VELOCITY AND LIGHT.—A subscriber of the *Popular Science News*, inquiring what is the velocity of light, that journal replies: "As determined by Foucault, it is 185,157 miles a second. This determination is undoubtedly very nearly exact, although the mechanical difficulties in the way of measuring such an immense velocity render it difficult to obtain perfectly accurate figures."

STELLAR DIAMONDS.

A SUGGESTION AS TO THE METEORIC ORIGIN OF THE DIAMOND.

Of all the curiosities which the wise men of the Association for the Advancement of Science brought to Washington for exhibition to their fellows, the most extraordinary was a meteorite with diamonds in it. Such a thing had never been seen or heard of before; in fact, it was the only specimen of the kind thus far discovered in the world. The diamonds were little ones, but what they signified was big. The meteorite in question was one of many found recently in Arizona, near the Cañon Diablo. It was supposed by the discoverers that they had hit upon an iron mine of enormous value, but investigation proved that the great chunks of metal picked up had been shot out of the realms of space. The place whence they were obtained is known as the "Crater," because it looks like one; being a circular hollow one hundred feet in depth, three quarters of a mile wide, and surrounded by a wall of rock so steep that the bottom is strewn with the skeletons of animals which have got in and been unable to climb out again. Nevertheless, it is not of volcanic origin, as is proved with certainty by the fact that there is no lava, obsidian—volcanic glass—or other volcanic products in the neighborhood. What was it then that made the crater? Geologists say that it was formed by the impact of a single gigantic meteor, which at some time in the past struck the earth and burried itself out of sight, leaving a hole which has since become partly filled up, surrounded by a wall of rock that was forced out of place. Imagine what a big one it must have been to leave a cavity three-fourths of a mile in width where it hit this planet. The huge mass of iron of which it was composed is there yet, of course. Perhaps it is not sunk too deep to render mining for its material unprofitable. Fragments of it formed the masses that were picked up by the prospectors above referred to. That one which contained the diamonds, however, has opened an absorbing subject for speculation. It proves that there are diamonds in other worlds than ours; but also it points to many other important conclusions. The diamonds of the famous Kimberly mines, which at present produce almost the entire world's supply of these gems, are all found at the bottoms of just such craters as the one described in Arizona. It is believed that these craters, so called, were formed by the impact of great meteors, because there is no other conceivable way in which they could have been made, and for other reasons geological. If so, then it must be inferred that probably all the diamonds of the world were brought to this terrestrial sphere by meteorites. In other words, these precious jewels are not native to the earth, but have been fetched hither with the dust of other stars. That accounts for the manner, hitherto deemed unaccountable, in which they are scattered everywhere through drift of all sorts, having apparently no birthplace or definite relation to other minerals. Some scientists go so far as to assert that diamonds, like coal, which is so nearly of the same chemical constitution, could not possibly come into existence without previous vegetable growth to generate their material. For this reason they infer that the finding of the gems in the meteorite demonstrates that there must have been vegetable life, at all events, in the place whence the meteorite came. If there was vegetable life there, it is a fair presumption that there was animal life also. All this may be untrue, but it affords the first guess glimpse that has ever been obtained into the greatest problem that mankind has ever attempted to handle, namely, the question whether life exists in other worlds than ours. From the philosophical point of view, the fact cannot but be taken for granted in a universe in which the sun is merely an inferior star of the fourth magnitude. Nevertheless, some absolute evidence on the point would be extremely satisfactory. Meteorites ordinarily are nearly all iron, with a small percentage of nickel. None of them has ever been known to contain a particle of any precious metal. Nevertheless, many of them are worth many times their weight in gold, because of some peculiarity of structure or otherwise. Every collector of minerals makes it a matter of pride to have a specimen of every known kind of meteorite in his cabinet. If a new sort turns up and he has not a piece he is unhappy. It happens sometimes that one weighing not more than a pound, of a make-up that has not been seen before, will sell in bits for a couple of thousand dollars if its possessor knows how to dispose of it. People are not less interested in other worlds because they know nothing about the next one.

LIQUEURS.

SOME THAT CAN BE MADE AT HOME.

Home-made liqueurs, like home-made syrups, says a writer in the *Queen*, are easily manufactured, and always much appreciated. One of the most important points in their making is the final process, which in most cases consists in filtering the cordials, and the success of the operation largely depends on it being carefully performed; therefore, it is perhaps not unwise to mention it at once. It must be done either through a felt bag or through paper. In the first case, turn a wooden stool upside down and tie the bag to the feet of the same, and well over the centre of a glazed pan. In the latter case, take a sheet of filtering paper (unglazed), twist it funnel-wise, and put it into a metal funnel, to line it, so to speak; or tear up some papier-mache, soak it in water, cut it up again, dispose a layer of these damp shreds on a hair sieve, and filter the liqueur through this arrangement. In every case pour back the first strainings till the liquid becomes quite clear.

RATAFIA DE PECHES.—Put into an earthenware jar the broken stones (both parts) of three or four dozen peaches and add a pinch of powdered cochineal. Cover this with about three quarts of spirits, tie the jar down and infuse about twenty days. Strain and add to each one and a half pints of juice about three pints of clear syrup (30 deg.), filter, bottle and cork. Or, stone some small peaches, cut them up, and squeeze them in a cloth to express all their juice. To each one and a half pint of this allow three pints of spirits, add a stick of vanilla, and let it all infuse in jars for six weeks on a shelf or ledge outside somewhere where they can get all the sun possible. Strain and add a little less than one pound of syrup (30 deg.), filter, etc. Or, skin and halve half a dozen peaches, break the stones and blanch the kernels. Place these peaches in layers in large glass jars, cup-wise, and in every alternate half peach put one of the kernels. Sprinkle them once or twice during the stacking with a half-pound of sugar, leaving some for the top. Let them stand overnight, then add one and a half pints of pale brandy and half a pint of syrup. Tie down and leave for a month, then add one pint of spirits, and filter, when wanted, in the necessary quantity for the occasion.

NOYEAU.—Take a quart of pure brandy, six ounces of clarified syrup, one ounce of French prunes (beaten with a mallet to break the stones), the bruised kernels of peaches, nectarines or apricots (two ounces), some grains of celery seed, a few drops of essence of lemon or bitter almond. Infuse all this for ten days at least, and filter, having previously added half a pint of filtered water.

RATAFIA DE CASSIS (BLACK CURRANT).—Half fill a stoneware jar with the currants, add a handful of their own leaves, some cinnamon and cloves; fill the jar with spirits, cover or cork, and infuse for six weeks as above, strain, and stir in about half pint of syrup (30 degrees) to each pint of liqueur; filter, bottle and cork. Or mix and infuse, as above, only for a fortnight. Strain and boil the berries with some red wine and sugar, make a syrup with the first strained juice and some sugar, add to this the strainings of the berries just stewed with wine, boil the mixture till it has reduced a little, and bottle as soon as cold. This is not so fine as the first recipe as a liqueur, but it is excellent for colds and sore throats.

CHARTREUSE.—This requires the very best spirits and the finest essences. (Good kirchwasser may be used.) To a quart of spirits add twelve or fourteen drops of absinthe, four of cinnamon essence, four of essence of roses. Make a syrup with one pound of sugar and one quart of water. Skim it, boil again till it is a little thicker, and reduced by one-third, and when cool mix it with the spirits, etc. Filter and bottle.

HUILE, OR LIQUEUR AU CAFE.—To each pint and a half of spirits allow 125 coffee berries, moderately roasted. Make a syrup (30 degrees) with one pound of good Demerara sugar; put the coffee into this, let it boil up two or three times briskly, and with hardly any interval, and pour it into the spirits. Bottle the mixture (berries and all), cork, seal, let it stand for a month at least, then filter, etc.

GERM DISEASES AND DISEASE GERMS.

Many of the recent discoveries in microscopic pathology are as curious as they are interesting. Thus, for example, the germs which produce a disease in a human being may have no effect upon other species of animals. A cow will drink water with impunity that is full of scarlet fever germs, and will transfer these to its milk, so that the disease may be carried in this manner from a country town where the ailment is epidemic, to a city a hundred miles away. Parrots will carry the germs of yellow fever in their plumage, and canary birds and kittens those of diphtheria and croup for days at a time, and for long journeys. In fact, just as nature distributes the seeds of valuable plants, herbs and trees, by the aid of living creatures, so in the same manner she scatters broadcast the germs of countless microscopic beings, which, when they attack humanity, produce disease, suffering and death. Of greater value is the fact that the power of germs to do harm depends mainly upon the condition of the system which they attack. Upon a person in robust health they have no perceptible effect, or else if they gain a foothold, the resulting disease is so slight as to be barely recognizable. On the other hand, when the body is in bad shape, they gain a lodgement with the greatest ease and the ailment assumes serious proportions. When the organization is in what may be termed a typhoid state, the illness becomes virulent or malignant. The different classes may be illustrated by different forms of the same disorder: Summer complaint, colic, cholera morbus, dysentery and typhoid dysentery The first is a mere incident, unworthy of notice; the last is a dangerous and too often a fatal malady, while the intermediate stages are more or less perilous, according to the state of the sufferer. It is for this reason that people who are scrofulous, debilitated, or anemic, suffer so much more when sick than those who are strong. The system is in a weak, and it may be a morbid condition, and the microbes multiply and thrive until nearly every tissue is affected. Persons of this type die off like sheep in the shambles, where vigorous men and women recover in a few hours. To render the system proof against these insidious seeds of sickness and death, it must be cleansed within thoroughly and the vital organs must be strengthened and made normal in action. This is a simple but gradual task. The skin must be kept so clean as to give the pores full scope; enough exercise must be taken daily to keep the joints and muscles in proper order and the appetite and digestion up to the mark. Then, and most important of all, the individual should use Ayer's Sarsaparilla until the blood is pure and the great physical functions are acting naturally. This is readily

determined at a glance. When the whites of the eye are clear, the complexion good, the tongue free from coating, and a spirit of buoyancy prevails, the system is then in good running order. Until then, the Sarsaparilla should be employed with the greatest regularity and care. Without these precautions, any one is liable to be stricken down with some germ disease at a moment's notice. With them, the germs find no foothold in the body, and the diseases they produce remain unknown. Judiciously used, Ayer's Sarsaparilla is the best known preventive of all these terrible ailments.

BUSINESS NOTES.

A RISING WESTERN CITY.

WATERTOWN, S. D., Aug. 20, 1891.—Here I am on the shores of Lake Kampeska, where the Indians claim that Gitche Maniton, the "Great Spirit," has addressed the Sioux Indians for many ages. This is said to be the most beautiful lake in the country—an inland ocean of fairy charms. The lake is fed by artesian springs from subterranean seas. Beginning on the northern shore of this lake, and running in the shape of a V, is the great Sisseton reservation, the lingering home of the Sisseton and Wampeton Indians, and comprising 3,000,000 acres of the choicest and richest blue grass land in the known world. This reservation will be opened to settlers within the next sixty days and it is safe to say that within the next six months thousands of families will have secured homes at settlers' prices, which in three years' time will be worth from $50 to $100 per acre, and which will yield every year the value of the farm in the rich products of the Northwest. The government agent is now paying the Indians for this land, and thousands of men, women and children are gathering on the border, waiting to cross over into the promised land. In this great Sioux Valley, crops never fail; here they have never known a drought. The average yield brings the farmer nearly the value of his land every year, and this is something which can be said of but few locations in the world. The old chief of the Dacotahs said, in addressing his braves, a few days ago: "Brave Dacotahs can no longer hope to hold beloved Kampeska." At the south point of this reservation, in Lake Kampeska is a huge rock known as "Prophet Rock." There has been from the birth of time among these Indians a legend that, so long as this rock remained above the water so long would the Indians retain the land, but that when it should sink beneath the waves the white man would possess it and hold sway." Strange as it may seem, this rock has been gradually sinking for the past ten years, and now as this reservation is being opened up by settlers and the Indians' title is being extinguished, this rock has sunk beneath the water.

"Sing, O, Song of Hiawatha,
Of the happy days that followed
In the land of the Dakotas,
In the pleasant land and peaceful,
Sing the mysteries of Mondamin,
Sing the blessings of the Cornfield,
Buried is the bloody hatred,
Buried is the dreaded war club,
And the war cry is forgotten.
There is peace among the nations."

These are the waters of which Longfellow wrote, Mrs. Sigourney poetized and Nilsson sung her sweetest song:

"Fascinating Lake of the heavens,
Waves of the setting sun,
Springs from an internal ocean
Whither go you and from whence did you come."

Lake and country of poet and poetess, singer and songstress soon to be a valley fit for gods. On the shores of Kampeska a city is arising as by magic. Twelve years ago not a white man within 125 miles of Kampeska; to-day, in a rich and prosperous agricultural valley of the richest land in the West, and on the shores of this lake, is Watertown, a city of 6,000 inhabitants, and a better built city than I have ever seen in the East of three times its size. As a manufacturing city Watertown is destined to rival Minneapolis and Omaha in a very few years. It is in the centre of the richest farming country of the West, a country which has made thousands of farmers wealthy in one year. A professor of the State University, writing to a Detroit paper a short time ago, said: "I am standing on the porch of the house of an old friend who left Michigan five years ago for Watertown, S. D. He arrived in this country with a team of horses, six children, and less than $100 in money. To-day he owns 1200 acres of the richest and most beautiful land man's eyes ever rested upon. He doesn't owe a dollar, his land is worth $60 to $70 per acre, he has in his granary 8000 bushels of last year's wheat, will harvest this year 17,000 bushels more, and his fields are covered with the finest stock. From where I am sitting I can see half a dozen other farmers as prosperous as he. In this country the farmer is monarch, the toiler of the soil, is king." Recently a syndicate was formed composed mostly of eastern men (though several prominent western men are interested in it), called "The Watertown Land and Improvement Company." Its officers are in this city, and in the Equitable building, Boston, Mass. This Company purchased in June last nearly half of the city of Watertown, and several thousand acres adjoining land, and control the shores of Lake Kampeska and Lake Pelican. This company offers every inducement to manufacturers to come to what promises to be a second Chicago. Five railroads are said to be in the deal. Several of the car shops are coming here and nearly a dozen factories have been arranged for. Books, maps and charts of Watertown and the Sioux valley are furnished upon application at the Company's office in Boston. They have already aided numerous farmers in getting homes in this richest of all lands. Their plan is to make Watertown, at the earliest possible day, a city second to none in the Northwest.

Buffalo Lithia Water, Spring No. 2, in Bright's Disease, Gout, Stone in the Bladder, and Diseases Generally of Uric Acid Diathesis, Etc., Etc.

DR. WM. A. HAMMOND, of Washington, D. C., Surgeon General U. S. Army (retired), Professor of Diseases of the Mind and Nervous System in the University of New York, etc.

"I have for some time made use of the BUFFALO LITHIA WATER in cases of AFFECTIONS of the NERVOUS SYSTEM, complicated with BRIGHT'S DISEASE OF THE KIDNEYS or with a GOUTY DIATHESIS. *The results have been eminently satisfactory.* Lithia has for many years *been a favorite with me in like cases, but the* BUFFALO WATER CERTAINLY ACTS BETTER THAN ANY EXTEMPORANEOUS SOLUTION of THE LITHIA SALTS, and is, moreover, better borne by the stomach. I also often prescribe it in those cases of CEREBRAL HYPERÆMIA resulting from OVER MENTAL WORK—in which the condition called NERVOUS DYSPEPSIA exists—*and generally with* MARKED BENEFIT."

DR. WM. B. TOWLES, Professor of Anatomy and Materia Medica, in the Medical Department of the University of Virginia.

"BUFFALO LITHIA SPRINGS, No. 2, belongs to the ALKALINE or, *perhaps, to the* ALKALINE SALINE Class, *for it has proved far more efficacious in many diseased conditions than any of the simple* ALKALINE waters.

"*I feel no hesitancy whatever in saying that in* GOUT, RHEUMATIC GOUT, RHEUMATISM, STONE *in the* BLADDER, and in all diseases of URIC ACID DIATHESIS, *I know of no remedy at all comparable to it.*

"*Its effects are marked in causing a disappearance of* ALBUMEN *from the urine. In a* single case of BRIGHT'S DISEASE *of the* KIDNEYS, I witnessed *decided beneficial results from its use, and from its action in this case I should have great confidence in it as a remedy in certain stages of this disease.* In DYSPEPSIA, especially that form of it in which there *is an excessive production of* ACID *during the process of nutrition*, in some of the PECULIAR AFFECTIONS *of* WOMEN, notably in SUPPRESSION of the MENSES, and in CHRONIC MALARIAL POISONING, etc., I have found it highly efficacious."

DR. G. HALSTEAD BOYLAND, late Professor of Surgery, Baltimore Medical College, late Surgeon French Army (Decorated), Member Baltimore Academy of Medicine, Member of American Medical Association.

"In BRIGHT'S DISEASE of the KIDNEYS, ACUTE or CHRONIC, BUFFALO LITHIA WATER, Spring No. 2, is, in my experience, *without a rival*, whether in the PARENCHYMATOUS form or INTERSTITIAL NEPHRITIS. In cases in which the ALBUMEN in the URINE reached as high as 50 per cent., I have known it under a course of this water gradually diminish and finally disappear, at the same time other alarming symptoms were relieved and the sufferers restored to health.

"In STONE in the BLADDER of the RED LITHIC ACID and the WHITE PHOSPHATIC DEPOSIT, the SOLVENT power of this water is *unmistakable*."

Water in cases of one dozen half gallon bottles, $5.00 f. o. b. here.

THOS. F. GOODE, Proprietor, BUFFALO LITHIA SPRINGS, VA.

WELL SPREAD.—A pound of phosphorus is sufficient to tip 1,000,000 matches.

ROSE LEAVES.—It requires about 3,000 pounds of rose leaves to produce an ounce of atter of roses.

LA GRIPPE.—The name "grippe" is supposed to be derived from the Polish word "chrypka," meaning catarrh.

YANKEE INGENUITY.—Connecticut last year took out more patents in proporton to population than any other State in the Union.

EARLIEST MILL.—It is said that the first mill to be operated by water power was invented by Mithriadates, king of Cappadocia, about the year 70 B. C

NEW CLAWS.—It is a fact not generally known that lobsters and several other crustaceans will renew a claw should one be lost in fighting or by accident

SUN LORE.—The sun is so large that, although its distance from us is nearly 93,000,000 miles, yet only a little more than 100 suns laid in a row, touching one another, would reach the earth,

NEW COMPOUND.—A German scientist has discovered a curious gaseous compound, made up of oxygen and hydrogen. It dissolves metals, and with silver and mercury it forms powerful explosives.

ORIGINAL. No. 46.

Breakfast Vanities

BY MRS. DEARBORN,

Principal Boston Cooking School.

Mix and sift together 1 pint pastry flour, ½ tea sp. salt and 1 heaping tea sp. Cleveland's Baking Powder. Mix to a stiff dough with milk, using only sufficient to make it stiff enough to roll.

Toss out on a slightly floured board, roll out very thin, cut into small squares with a sharp knife or pastry wheel and drop into boiling lard.

Shake the kettle gently to facilitate their rising, and when well puffed up turn them and brown the other side. Drain on paper. They should be cooked in fat hot enough to brown a piece of bread while counting sixty, and are quite hollow when cooked. Serve with maple syrup if liked.—(Copyright, 1891.)

Use only Cleveland's baking powder, the proportions are made for that.

Pure crystal cream of tartar and soda make a perfectly wholesome leaven. There is no other leavening power in Cleveland's Baking Powder.

Fine Table Wines

Short-sighted

—the woman who doesn't use *Pearline;* the woman who fails to have her servants use *Pearline.*

She fails to see what is good for her; she fails to have what is best for her.

Without *Pearline*, washing and cleaning is drudgery and toil, and wear and tear, and rub, rub, rub.

With it, there is no hard work, and no harm to the finest things; there is little or no rubbing.

Use *Pearline*, and rest from your labor; the rest of your labor—the hardest part—is done by *Pearline.*

Fore-sight

The woman has fore-sight who refuses the imitations of Pearline offered by peddlers and unscrupulous grocers, which they claim to be "same as Pearline," or "as good as Pearline." IT'S FALSE—besides, Pearline is never peddled

243 JAMES PYLE, New York.

COPPERED IRON.—A process has been recently invented by which iron may be coppered by dipping it into melted copper, the surface of the iron being protected by a layer of melted cryolite and phosphoric acid. It has been found that if the article, when immersed, is connected with the negative pole of a battery, the coppering is done more rapidly.

MAGNETIC CONCENTRATOR.—A new ore concentrator has been devised, which operates by crushing the material to about a quarter of an inch in size, and which, exposed to the action of powerful magnets, separates the particles of iron ore. The particles of ore are again crushed to a finer state, and again exposed to magnetic action, resulting in a concentrated condition of the iron.

SIMPLE ENGINE.—For users of steam power, who are not skilled mechanics or not accustomed to run engines, a unique type of engine construction has, says the *Safety Valve*, lately come into vogue, consisting of a moving steam cylinder and moving valve, and a stationary steam chest, thus dispensing entirely with various mechanical arrangements, commonly employed, such as the eccentric valve rod, complicated connecting rods, slides, rockers, etc.

SUN BURST.—A luminous outburst of the sun was observed by the French astronomers on the 17th of June. First appeared a luminous spot of a yellow golden tinge, soon followed by another just above it. The spectroscope showed the first spot to consist of a central eruption, from which volcanic bombs were thrown to heights above the chromosphere, where they seemed to rest as dazzling balls. A few minutes later these were replaced by brilliant jets or filaments.

MAMMOTH FLAG.—On Friday, Septemper 11th, the Overman Wheel Co., Chicopee Falls, Mass., flung to the breeze one of the largest United States' flags ever made (and possibly the largest), the dimensions being 41x71 feet. This monster flag was stretched from the top of two five story factories, and gathered within the folds were numerous flowers which fell into the crowd below when unfurled. The Mayor of Chicopee, the Overman Wheel Co. Band, and a large concourse of spectators witnessed the event. The flag is without advertising of any kind, being merely a national flag.

SKY COLOR VARIATIONS.—An interesting paper detailing observations on the variation of the intensity of the blueness of the sky was recently read before the Academie des Sciences, Paris. The observations were made at Montpelier, France, and may be summarized as follows: The sky is bluest in the months of December, January, March and September and least blue in February, July, August and November. Speaking in general terms the sky is deepest blue in Winter, palest blue in Summer and of intermediate depth of color in Spring and Autumn. With regard to each day, the sky is bluest in the morning and palest during the hottest hours. Toward evening the blue intensifies again, but does not equal that of the morning.

Armour's

Extract of BEEF.

The best and most economical "Stock" for Soups, Etc.

One pound equals forty-five pounds of prime lean Beef.

Send to us for our book of receipts, showing use of ARMOUR'S EXTRACT in Soups and Sauces.

TABASCO PEPPER SAUCE,

OR LIQUID PEPPER.

Is simply the Pulp of the Ripe Pepper Extracted by Pressure.

The seed of this Pepper was obtained from Central America, and by careful cultivation in Louisiana for many years has been so improved in strength, flavor and aroma, as to have become a new variety of Red Pepper, superior to all others. The pulp is so handled as to retain all the flavor, strength, aroma and color of the ripe fruit, and to keep unimpaired in any climate. It excites the appetite, promotes digestion, and is pronounced by connoisseurs to be the finest condiment in the world. For medicinal purposes it recommends itself by its purity, strength and diffusible form.

Manufactured by E. McILHENNY'S SON,

NEW IBERIA, LA.

For Sale by all Wholesale Grocers.

WATERTOWN, SOUTH DAKOTA.

THE MARVELLOUS RESULTS which have been accomplished in the rearing of cities and towns upon the fertile plains of South Dakota, seem, at times, to overreach the imagination of the most visionary mind. Those who are accustomed to the vim, the pluck, the shrewdness, and the far-reaching plans of the Westerner, are sometimes found meditating in wonder at the rapid development on every side of them, while men more accustomed to Eastern environments and ideas, and to less rapid progress, look in awe and amazement at the work of hardly a decade.

Ten years ago, where now stands the city of WATERTOWN, there was nothing to obstruct the vision from a great ocean of rolling prairie in one direction, from the winding and fertile Sioux Valley in another, or from the rivers and lakes on the west; there was not the sign of a tree in sight, save those which skirted the borders of Lake Kampeska, and one could count on the fingers of one hand the white men then here.

IN 1884,

WATERTOWN consisted of a straggling little town of 50 or 60 buildings of which the following is a bird's eye view.

To-day a city of Brick, Stone and Granite, with 6,000 Souls,

eight lines of railway, miles and miles of graded streets and sidewalks, shade trees, numerous manufacturing plants, water works, street-car lines, electric lights, five-story hotels, opera houses, churches, schools, financial exchanges, jobbing and mercantile interests, parks and boulevards neat, cosey, and comfortable homes; a city whose corporate limits extend over an area of four sq. miles, which is but poorly illustrated below.

WATERTOWN IN 1891.

With unsurpassed R. R. facilities for business (8 lines now entering there and 2 more already projected) and most delightful residence sites especially cheap and available; adapted to suit the tastes of either rich or poor, it offers inducements to Business Men, Manufacturers, Capitalists and Home Seekers, seldom found. Its Educational advantages are first-class as can be judged from the view below of the

NEW HIGH SCHOOL BUILDING.

In a future issue we shall offer further proof of its growth, by views of some of its Public Buildings, and also show the

MARVELLOUS AGRICULTURAL AND MINERAL RESOURCES

of SOUTH DAKOTA, and the value of WATERTOWN as a **Market and Distributing Centre** for manufactured goods as well as agricultural products. MAPS AND ILLUSTRATED PAMPHLETS giving full statistical details, and describing the lands for sale adapted for Residences, Business, Manufacturing or Agricultural purposes, sent **Free to any Address.** Apply at the offices of the

DO YOU KNOW THE **DANGER** OF USING SOAP?

We do not mean soap made from proper material; and when we tell you that about ninety-nine per cent. of Toilet Soap is made from refuse fats gathered from tenement houses, hospitals, butcher shops, and from cattle dying of disease or during transportation, you will, we believe stop and think. Putrefactive changes have taken place in most of this material, as it is mixed with lean meat, blood, bones, sinews, etc. There is at least *one* soap that is made wholly from vegetable material—OLIVE and PALM OILS—and that is

VELVET SKIN SOAP.

It will keep the skin soft and in a healthy condition, as no animal fats are used in its manufacture. Nothing in one's personal outfit is quite so satisfactory as a thoroughly reliable Toilet Soap. We are confident that a trial of this article will insure its continued use. If the dealer does not keep it, do not take any other, but require him to order it for you, which he can do readily. **Otherwise, send to us direct.**

MANUFACTURED BY

REED & CARNRICK, Manufacturing Chemists,

447 GREENWICH STREET, NEW YORK.

GLENN'S **SULPHUR SOAP.**

Glenn's Sulphur Soap is the **Original and Best** combination of its kind, and the one now generally in use. For sale by **All Druggists.**

THE QUEEN'S PRIZE SCHOOL OF HISTORY.

About two years ago the publishers of THE CANADIAN QUEEN added what has proven to be a very popular and successful feature to their publication in establishing their Prize History School. It has offered competitive examinations in English, Canadian and American History, giving valuable rewards to those making the most correct answers. During this time there have been added the names of over forty thousand new subscribers to their books. Rewards have been made by THE QUEEN which have cost them in cash over ten thousand dollars. THE QUEEN'S Prize School of History has received the sanction and support of the clergy, press, and, in fact, of the best people of the Dominion of Canada. The following, taken from a leading daily newspaper, expresses an opinion which is universal:

A HANDSOME PRIZE.

AN EVIDENCE OF WHAT A GENUINE MAGAZINE COMPETITION OFFERS.

"On Friday there arrived from Toronto, for Miss M. Hora, a handsome Shetland pony, harness and cart, being the first award in the Royal Quilt Competition of THE CANADIAN QUEEN magazine. It attests the genuine nature of the magazine's contests by its excellent condition and value. THE QUEEN has frequent competitions and has made innumerable awards, displaying a generosity quite surprising to those who have had experience of the limited field for Canadian journalistic enterprise. But THE QUEEN has been a success as a business venture from the start, and is growing in literary excellence steadily. It covers the field of fashion, as well as light reading; talks to the household, the young, and, indeed, all home classes. The competitions have been used to assist the introduction of the magazine, for where it is introduced it is quite certain to remain a monthly guest. The leading prizes have been made, as instance this latest to Kingston, while many smaller prizes have rewarded the moderately successful among competitors. THE CANADIAN QUEEN is truly royal in its ways."—*The (Kingston, Ont.) Daily British Whig*, June 27th, 1891.

QUESTIONS IN AMERICAN HISTORY.

1.—Give the names of the early navigators who it is claimed by historians first discovered America.
2.—From whom has America taken its name?
3.—What class and nationality first settled Virginia? New York? Massachusetts? Pennsylvania? Maryland?
4.—What action did the Continental Congress of 1774 take and what was the result of that action?
5.—What was the first battle fought in the War of the Revolution?
6.—What nation rendered the Americans great assistance in the War of the Revolution?
7.—Give the names of the committee appointed to draft the famous Declaration of Independence.
8.—What was the date of the signing of the United States Constitution?
9.—After becoming a nation and before the great Civil War, what were the principal conflicts which engaged the Americans?
10.—What was the direct cause of the Civil War? What Generals of the Northern Army have occupied executive positions under the Federal Government since the closing of the War? Who was Commander-in-Chief and who were the principal Generals of the Confederate Army during the struggle?
11.—How long did this War last and what is the computed loss of life?
12.—What can be said to day of the United States as a nation?

To the *First* gentleman sending the correct answers to the above questions in American History the publishers of THE QUEEN will present **"Majestic"** acknowledged the **Handsomest and Finest Riding Horse in Ontario.** ("Majestic" is sixteen hands high, thoroughbred, seven years old, and valued at $350.00.) To the *First* lady the publishers of THE QUEEN will present an elegant **Jacket of Genuine Alaska Seal** to be made according to the measurement supplied by the winner. To the *First* boy under sixteen years of age the publishers of THE QUEEN will present a **Little Giant Safety Bicycle** valued at $75.00. To the *First* girl under sixteen years of age the publishers of THE QUEEN will present an elegant **Music Box,** playing twenty tunes, finely finished and valued at $55.00.

To the gentleman from whom the *Last* correct answers are received before the close of this Competition, the publishers of THE QUEEN will present a **First Cabin Passage to Europe and Return** and **$200 in Gold** for expenses. This trip can be taken by the winner any time before October 1st, 1892. To the lady from whom the *Last* correct answers are received before the close of this Competition the publishers of THE QUEEN will present a **Pony, Cart and Harness.** To the boy under sixteen years of age from whom the *Last* correct answers are received before the close of this Competition the publishers of THE QUEEN will present a **Solid Gold Watch** containing one of the best American movements, and valued at $75.00. To the girl under sixteen years of age from whom the *Last* correct answers are received before the close of this Competition the publishers of THE QUEEN will present an elegant **Solid Gold Watch,** containing one of the best American movements, and valued at $65.00.

ADDITIONAL PRIZES IN ORDER OF MERIT: Silver Tea Services, Ladies' Gold Watches, Silk Dress Patterns, French Mantel Clocks, Portiere Curtains, Toilet Cases, Manicure Sets, and many other useful and valuable articles.

The object of the publishers in offering these liberal prizes is to introduce THE QUEEN Magazine into **new** homes. Answers must be mailed *on or before* November 10th, 1891, and must be accompanied by $1.00 for one year's subscription to THE CANADIAN QUEEN. Prizes awarded to subscribers residing in the United States will be shipped to them **free of duty.** The distribution of awards is in the hands of disinterested persons, and decisions will be based on the correctness of answers. Use your own language in wording the answers. No corrections can be made after your answers are mailed. THE QUEEN is a large, forty-eight page family magazine, especially interesting to ladies and children, and visits regularly **over one hundred thousand of the best homes** in Canada and the United States. The awards in THE QUEEN'S Prize School of History are made strictly with regard to merit, without partiality to persons or locality. The decisions must be accepted as final. If you have never seen a copy of THE QUEEN send six U. S. two cent stamps and receive a late number, post paid, containing letters from those who have received rewards in previous contests.

Address THE CANADIAN QUEEN, PRIZE SCHOOL OF HISTORY, 58 BAY STREET, TORONTO, CANADA.

AN EDUCATION FREE! Do you want a good business education, including English Branches, Commercial Law, Business Forms or Book-keeping, or Shorthand and Typewriting, Languages, or Architectural or Mechanical Drawing, or Elocution **ABSOLUTELY FREE** in one of the largest, oldest and most prominent Business Colleges in the country? All you have to do is to get up Clubs for the **BUSINESS WORLD,** one of the brightest, newsiest and best office and home papers in the country. Established 14 years. Subscription price, with premium worth price of subscription, only $1.00 per year; handsomely illustrated. The BUSINESS WORLD will give Scholarships to those getting up Clubs. Write for particulars, **BUSINESS WORLD,** 15 WILCOX AVE., DETROIT, MICH.

WOMAN IN 1893.

The Board of Lady Managers of the World's Fair to be held in 1893 in Chicago has decided upon the general nature and arrangement of the contents of the Women's Building. Adjoining the main entrance will be a bureau of information, where visitors can secure answers to questions, and here girls and women as interpreters and guides will be supplied. In the main gallery will be a special exhibit of the most brilliant things women have done. Whenever it can be done, duplicates of especially fine work by women, shown in the main buildings, will be secured for the Woman's Building. The Bellevue Hospital of New York will probably have charge of the trained nurse department. Model kindergartens will be a conspicuous feature. Another room will show the literary work of women. There will be in another room a collection of quaint fabrics and rare old laces. A model kitchen will give practical illustrations of culinary methods and the newest appliances. In the second story will be a large assembly hall, which will be the scene of many meetings of importance to women. Here will also be a club room for women journalists. The committee and administration rooms will form the wings of the third floor, the roof garden occupying the centre.

MANY THANKS.

There is a little paper which arrives every week amongst my exchanges. It is called the AMERICAN ANALYST, and is published at 19 Park Place, New York City. When I say that there is no paper received by me that contains more varied or useful information I only tell the plain unvarnished truth. It only costs one dollar per year and is worth ten times that amount. To the housewife, it is full of useful hints and valuable receipts, and, in fact, is full of information which cannot but be profitably read by all. It is nicely printed and ably edited. You cannot spend a dollar with more profit to yourself than you can by securing this truly valuable paper. Try it.

The above pleasant notice of the AMERICAN ANALYST appeared in the September 19th issue of the *True Democrat*, a weekly newspaper edited by Mr. T. H. Graham, and published in Baltimore. We thank our Maryland contemporary for his appreciative and commendatory remarks. This journal is not often called to the attention of the public through political mediums, and in the present instance we recognize a special significance which imparts peculiar emphasis to the compliment. For a "true" Democrat, whether regarded politically or otherwise, must of necessity represent the loftiest type of humanity, a "true" man, and as such is a synonyme for "the noblest work of God." Hence our gratification.

BAMBOO CULTURE.

According to a Washington correspondent, our government agricultural bureau is interesting itself in fostering the cultivation of the bamboo, in the fond hope that it may yet be raised in this country, as it is in China, where it supplies a large part of the wants of the people, being applied to more than five hundred different and useful purposes. The useful applications of the bamboo are wonderful in their variety. In the Flowery Kingdom it takes the place both of iron and steel. The farmer builds his house and fences out of it, his farming utensils as well as his household furniture are manufactured from it, while the tender shoots furnish him with a most delicious vegetable for his table. The roots are carved into fantastic images, shaped into divining blocks, to guess the will of the gods, or cut into lantern handles and canes. The tapering culms are used for the props of houses, the frameworks of awnings, the ribs of sails and shafts of rakes, for fences, and every sort of frames, coops, and cages, and for the handles and ribs of umbrellas and fans. The leaves are sewed into rain coats and thatches. The wood, cut into splints of various sizes, is woven into baskets of every form, sewn into window curtains and door screens, and twisted into cables. The shavings and curled threads furnish materials for stuffing pillows, while parts supply the bed for sleeping, the chop-sticks for eating, the pipe for smoking, the broom for sweeping, the mattress to lie upon, the chair to sit upon, the table to eat on, the food to eat, and the fuel to cook it with. The ferule to govern with the book to study from, the reed pipe of the organ, the shaft of the soldier's spear, and the dreaded instrument of the judge; the skewer to pin the hair, and the hat to screen the head; the paper to write on, the pencil to write with, and the cup to put the pencil in; the rule to measure lengths, the cup to gauge quantities, and the bucket to draw water; the bird cage, the crab net, the fish pole—are one and all furnished by this plant, whose beauty when growing is commensurate to its usefulness when cut down. A score or two of bamboo poles for joists and rafters, fifty fathoms of rattan ropes, and a supply of palm leaves and bamboo mats for a roof, supply material for a common hut in the South of China.

AMMONIA IN BAKING POWDERS.

The Royal Baking Powder Company having for years fought shy of making any defense of its use of ammonia in baking powder has at last been driven in a corner, and in its usual disingenuous manner now causes reading notices to be published which pretend to give the transactions of the American Chemical Society. This is so garbled as to seem to convey the impression that the best chemists in the country have come to the conclusion that ammonia is a necessary ingredient in all baking powders, in fact, that any baking powder which does not contain this nauseous drug cannot be wholesome. Ammonia not only neutralizes any acidity but also serves to keep the bread fresh. It goes without saying that this is arrant nonsense gotten up by the paid chemists of the Royal Ammonia Company. Dr. H. Endemann has addressed a letter to the *Tribune* on the subject, in which he says: "I have just seen the report of the discussion at the Washington meeting of the American Chemical Society, August 18, relative to the use of carbonate of ammonia in baking powders. This report is incomplete and incorrect in many particulars, and as the paper which precipitated the discussion was read by me and was based upon my own experience, I desire to make certain corrections in the interest of the truth and for the benefit of the large number of your readers to whom the question is one of great moment. The paper as read before the society related that ammonia in baking powder is retained in the bread by reason of its affinity to the gluten. The consensus of opinion as expressed during the discussion was against the use of carbonate of ammonia in baking powder with the only exception of Dr. McMurtrie, who is now an employee of a baking-powder com-

pany which uses carbonate of ammonia in its baking powder. Of the other parties mentioned as having taken part in the discussion were Professor Dr. Barker, of the University of Pennsylvania, who is the president of the society and one of our highest authorities. In answer to a pleading by Professor McMurtrie that only small quantities of ammonia were used in baking powders, he stated: 'No matter how small the quantity, I must decline to be dosed medically without my consent when taking my meal's. Dr. E. H. Bartley, formerly chemist of the Brooklyn Board of Health, and Professor of Chemistry at the Long Island College, likewise named, did not, I believe, take active part in the discussion, but is already on record as strongly opposed to the use of ammonium carbonate in baking powders. Dr. Richardson volunteered only the question whether the flour used in the experiments was of good quality, of which I assured him by stating that it was the best, and the flour used in my family. Professor Mallet was not present. Your article is misleading in so far as it gives the impression that ammonia disappears on baking. My actual tests agree with those made by others, showing that ammonia remains in the bread. My investigations simply assign a new cause for its retention."

THE WEAKER SEX.

WHICH REPRESENTS IT, THE MAN OR THE WOMAN?

The subjoined discussion of the share of the family toil that falls to the lot of woman in the middle sphere of life, is respectfully commended to the attention of the fair representatives of the "Four Hundred" constituting the uppermost sphere: It seems to be accepted as a fact that woman in contrast with man is far the weaker. The reasons for it are not quite clear, and perhaps to frequent repetition it owes its greatest force. In the matter of brute strength certainly to women must be given second place, but when it comes to endurance, which is scarcely separable from strength, in many situations in life she would most assuredly show herself able to bear far heavier burdens than man. Probably nowhere else is this truth as apparent as in the sick-room. There man and woman meet on an equal footing, neither having any advantage. And it is there that she proves that instead of being the weaker she is infinitely the stronger and more enduring. Let a wife be taken ill, and for twenty-four hours the husband is untiring in his devotion, and very likely he scarcely leaves her bedside. The second day finds him still at his post, but he is beginning to weaken, even the loss of one night's sleep has nearly "broken him up." But the third day he is comparatively a wreck, and ready to yield his place as nurse to any one who will fill it. Not so, however, with the wife when he is ill. Day after day and night after night she hangs over him, never for a moment thinking of intrusting him to the care of another. If she sleeps, it is in her chair by his bedside while he dozes. She scarcely lies down, and perhaps for weeks and weeks only removes her clothes for a change of linen. And yet she never seems to tire; and, as a matter of fact, many frail women seem actually to gain strength when exposed to such hardships. The world may accept that woman is the weaker, but no physician who has been long in practice will be convinced that such is the case. Man compares with woman as does cast iron with steel. He is strong, and yet is comparatively easily shattered, whereas you can bend her, you can put her to tests which would, figuratively speaking, pulverize him, and yet you cannot "break her up." Take her outside of the sick room. She is—at least many married women are—up first in the morning. She builds the fires and makes breakfast ready. Before the table can be "cleared off" her children must be scrubbed, combed, etc., for school. With them out of the house, unless there is a baby in the family—and there almost always is one in the home of every poor, overworked woman—she has a breathing spell. But it cannot last long, for there are the dishes to wash, the kitchen to "tidy," the chamber work to do, and when these and other customary duties are performed it is time to get dinner. That ought to be off the table and "things put away" by two or half past two, and then she has reached her first opportunity to rest. But she does not rest, although she may think she does, for she generally sews until supper time and returns to her sewing after supper dishes are cleared away, and she is not likely to lay aside her needles until bedtime comes. But this is the routine work of only about one day in week. Very likely Monday is washing day, and on Tuesday there is the ironing to do. Wednesday is one of the cooking days with almost all women. Thursday is the day we have partially described, and is called the easy day. Friday the broom must be called into special service, and a general sweeping takes place. Saturday is one of the hardest days in the week, while Sunday—the day of rest for man and beast—finds the wife and mother still on duty, for the greater part of it at least. We have given but a bare idea of the common experiences of about three-fourths of all our women; with them it is work, work, day in and day out, with scarcely a moment which they can call their own; in fact, they work about sixteen hours a day. Husbands, on the other hand, consider even ten hours at bench, at the counter or desk too long for them, and really only feel equal to eight hours a day. Night finds them tired and worn, and the evenings must be spent in recuperating. On half time on Saturdays, and Sundays there being absolutely nothing for them to do, they, somehow or other, manage to "pull themselves together" by Monday, so as to take up their burdens again. The many holidays in the year help them out considerably; so they are enabled to bear the strain. And we style woman weak, while man is our ideal of strength. Could anything be more absurd? Let the average woman change places with her husband, and she would be a widow in a few years. Yet not only in health does woman show her superiority over man in the way of strength and endurance, but it is the same in disease. Attacks which man is likely to succumb to are less likely to prove fatal in woman. Perhaps in consumption, as well as any other malady, is the fact apparent. It is safe to say that, take a man and a woman in the early stages of lung disease, and if one attack be of the same severity as the other, the woman will outlast the man by many months, and possibly by years.

DEGENERATION AND EVOLUTION.

BIOLOGICAL CONSIDERATIONS OF PROCESS AND RETROGRESSION.

Mr. H. G. Wells, writing for the *Gentleman's Magazine* (London), says: Perhaps no scientific teaching has been exposed to a greater amount of popular misconception than the doctrine of evolution. In the popular conception, life began with the amœba, then came jelly fish, shell fish, and a miscellaneous mass of invertebrates; then real fishes and amphibia, reptiles, birds, mammals, and man, the last and first of creation. This is not the teaching of science. On the contrary, biology, along with advance, teaches retrogression as its essential complement. Isolated cases of degeneration have long been known. It is only recently that the enormous importance of degeneration as a plastic process in nature has been suspected and its entire parity with evolution recognized. In fact, the path of life so frequently compared to a steady ascent, an indication of an inevitable tendency to higher and better things, is distinctly repudiated by scientific observers. The sounder view is that living species have varied along divergent lines from intermediate forms and by no means necessarily in an upward direction. The best known, and perhaps the most graphic and typical illustration of the downward course, is to be found in the division of the *Tunicata*. The untrained observer would probably class it near the oyster and the mussel, and a superficial study of its anatomy might even strengthen this opinion. As a matter of fact, however, these creatures are far more closely related to the vertebrata, a fact exhibited in the details of their development. It is a matter of common knowledge that living creatures in the course of their embryonic development repeat, in a more or less blurred and abbreviated series, their generalized pedigree. For instance, the developing chick or rabbit passes through a fish-like stage, and the human fœtus wears an undeniable tail. In the case of these ascidians (the Tunicata) the fertilized egg-cell destined to become a fresh individual follows an entirely different course from that pursued by the molluscs; the dividing and growing ovum exhibits phases resembling in the most remarkable way those of the lowliest among fishes, the lancelot or *amphioxus*. The method of division, the formation of the primitive stomach and body cavity, and the origin of the nervous system are identical, and a stage is attained in which the young organism displays—or stimulates—vertebrate characteristics. It has a *notochord*, or primary skeletal axis; it displays gill-slits behind its mouth, as do all vertebrated animals in their earlier stages, and the origin and position of its nervous axis is essentially vertebrate. In these three independent series of structures the young ascidian differs from all invertebrate animals, and manifests its high descent from the vertebrates. It is an evident case of retrogression. Like a tadpole this animal has a well-developed tail, with which it propels itself vigorously through the water; it has serviceable sense organs, and appears in this, its earlier stages, to be full of vigorous, enjoyable life; but scarcely is this stage attained before the animal undergoes a process of retrogression. It develops suckers, by means of which it attaches itself to the rocks, its tail is absorbed, eye and ear atrophy, and the skin secretes the coarse inorganic looking "test;" the transient glimpse of vivid animal life is forgotten, and the creature settles down for life to a mere vegetable existence. In some cases the degradation has been a strategic retrogression—the type "stoops to conquer." This is, perhaps, most manifest in the case of the higher vertebrate animals. It is one of the best-known embryological facts that a bird or a mammal starts in its development as if a fish were in the making, and that later the organs get twisted and patched to fit a life out of water—nowhere organs built specially for this very special condition. There is nothing like this in the case of a fish. There the organs are from the first recognizable sketches of their adult forms, and they develop straightforwardly, but the higher types go a considerable distance towards the fish, and then turn round and complete their development in an entirely opposite direction. This turning is evidently precisely similar in nature, though not in effect, to the retrogression of the ascidian after its pisciform or larval stage. If a zoological investigator could have visited the earth during the upper Silurian period, and with prophetic eye could have singled out the ancestors of man, he would have found them, not among the dominant placoid fishes of the Silurian sea, but in the *Dipnoi* or mud fish, swimming in the pluvial waters, or inert and caked over by the torrid mud. He would have found in conjunction with the purely primitive skull, axial skeleton, and fin possessed by these Silurian mud fish a remarkable adaptation of the swimming bladder to the needs of the waterless season. It would have undergone the minimum amount of alteration to render it a lung, and blood vessels and other points of the anatomy would show correlated changes. Here we have the old story of degeneration over again; the mud fish had failed in the struggle, they were less active and powerful than their rivals of the sea, and they had taken the second great road of preservation, flight. Just as the ascidian has retired from an open sea, too

crowded and full of danger to make life worth the trouble, so, in the older epoch, did the mud fish. They preferred dirt, discomfort and survival to a gallant fight and death. Very properly, then, they would be classed in our zoologists' scheme as a degenerate group. But some of them have risen in the world again; they came out of the rivers, gave birth to the amphibia of the coal, which gave place presently to the central group of reptiles, from which sprang divergently birds and mammals, and finally the last of the mud fish family, man—the heir of all the ages.

THOSE GOOD OLD DAYS.

TABLE CUSTOMS OF OUR BRITISH ANCESTORS.

A thousand years ago, when the dinner was ready to be served, the first thing brought into the great hall was the table. Movable trestles were brought, on which were placed boards, and all were carried away again at the close of the meal. Upon this was laid the tablecloth, which in some of the old pictures is represented as having a handsome embroidered border. There is an old Latin riddle of the eighth century in which the table says: "I feed people with many kinds of food. First I am a quadruped, and adorned with handsome clothing; then I am robbed of my apparel and lose my legs also." The food of the Anglo-Saxon was largely bread. This is hinted in the fact that a domestic was called a "loaf-eater," and the lady of the house was called a "loaf-giver." The bread was baked in round, flat cakes, which the superstition of the cook marked with a cross, to preserve them from the perils of the fire. Milk, butter and cheese were also eaten. The principal meat was bacon, as the acorns of the oak forests, which then covered a large part of England, supported numerous droves of swine. Our Anglo-Saxon forefathers were not only hearty eaters, but, unfortunately, deep drinkers. The drinking-horns were at first literally horns and so must be immediately emptied when filled; later, when the primitive horn had been replaced by a glass cup, it retained a tradition of its rude predecessor in its shape, for it had a flaring top while tapering toward the base, so that it, too, had to be emptied at a draught. Each guest was furnished with a spoon, while his knife he always carried in his belt; as for forks, who dreamed of them when nature had given man ten fingers? But you will see why a servant with a basin of water and a towel always presented himself to each guest before dinner was served and after it was ended. Roasted meat was served on the spit or rod on which it was cooked, and the guest cut or tore off a piece to suit himself. Boiled meat was laid on the cakes of bread, or later, on thick slices of bread called "trenchers," from a Norman word meaning "to cut," as these were to carve the meat on, thus preserving the tablecloth from the knife. At first the trencher was eaten or thrown upon the stone floor for the dogs who crouched at their master's feet. At a later date it was put in a basket and given to the poor who gathered at the manor-gate. During the latter part of the Middle Ages, the most conspicuous object on the table was the salt-cellar. This was generally of silver in the form of a ship. It was placed in the centre of the long table, at which the household gathered, my lord and lady, their family and guests being at one end and their retainers and servants at the other. So one's position in regard to the salt was a test of rank—the gentlefolks sitting "above the salt" and the yeomanry below it. In the houses of the great nobles dinners was served with much ceremony. At the hour a stately procession entered the hall. First came several musicians, followed by the steward bearing his rod of office, and then came a long line of servants carrying different dishes. Some idea of the variety and profusion may be gained from the provision made by King Henry III. for his household at Christmas, 1254. This included thirty-one oxen, one hundred pigs, three hundred and fifty-six fowls, twenty-nine hares, fifty-nine rabbits, nine pheasants, fifty-six partridges, sixty-eight woodcock, thirty-nine plovers, and three thousand eggs. Many of our favorite dishes have descended to us from the Middle Ages. Macaroons have served as dessert since the days of Chaucer. Our favorite winter breakfast, griddle cakes, has come down to us from the far-away Britons of Wales, while the boys have lunched on gingerbread and girls on pickles and jellies since the time of Edward II., more than five hnndred years ago.

WATER GAS.

SO CALLED, THOUGH NOT MADE FROM WATER.

The above name is applied to a kind of gas which, in many cities, is largely used for illuminating and heating purposes. The cost of manufacture is, apparently, somewhat less than that of gas distilled from bituminous coal in the old way, and, for this reason, some gas companies have altered their plant so as to manufacture the water gas exclusively. The term "water gas" is misleading, for water does not contain any of the gas, although it is used in the process of manufacture. The use of such a name tends to confirm the erroneous belief held by so many people, that, by some chemical process, water may be made to burn; and many have been the fraudulent inventions claiming to accomplish this impossibility. Water is a product of combustion, and all the chemical affinities of its constituent atoms are neutralized. It is a perfectly neutral, impassive body, and contains neither fire nor force. Water gas is the product of a peculiar chemical reaction which takes place when steam is passed over red-hot coals. The steam is decomposed by the carbon of the coal, and a mixture of carbonic dioxide, carbonic oxide, and hydrogen is the result. The reaction, expressed by chemical symbols, is as follows:

$$\underset{\text{steam.}}{4H_2O} + \underset{\text{carbon.}}{C_3} = \underset{\text{carbonic dioxide.}}{CO_2} + \underset{\text{carbonic oxide.}}{2CO} + \underset{\text{hydrogen}}{H_8}$$

The last two gases are inflammable, and constitute the valuable constituents of the mixture. Water gas, as constituted above, burns with a hot but non-luminous flame. It is exceedingly well adapted for use as fuel without further preparation, and, in some cities, is largely used for this purpose. To render it luminous, crude petroleum is allowed to flow into the retorts; and the heavy hydrocarbon vapors resulting from its decomposition so "enrich" the water gas that it is rendered as luminous as coal gas, and, after being purified, can be burnt from an ordinary burner in the same way. The only objection to the general use of water gas is the large percentage of carbonic oxide it contains. This gas is extremely poisonous when inhaled, and many cases of death from this cause have been reported. Coal gas contains a much smaller percentage of carbonic oxide, and, on this account, is less dangerous in case of an accidental leak. Considering the large number of consumers of water gas, however, the number of accidents has been so few that the danger would seem to be very slight. Water gas is also quite inodorous and without the characteristic smell of coal gas. A leak occurring in a building is thus likely to escape detection until a dangerous quantity has escaped. To remedy this fault it has been proposed to add a minute trace of mercaptan—a sulphur compound of an extremely offensive odor—to the gas. While this would not injure its illuminating qualities in any way, and would be perfectly inoffensive after being burnt, it would make its presence at once manifest in case of any accidental escape of the gas, and lead to the prompt repair of the pipes. In Massachusetts the amount of carbonic oxide in illuminating gas is forbidden by law to exceed a certain per cent.; consequently the use of water gas in the State is very limited. In most States, however, there is no restriction upon its composition, and the only reason that water gas has not come into almost universal use is probably due to the small difference between the cost of its production and that of gas distilled from coal in the old-fashioned away.

INSOMNIA.

EXPERIMENT RESORTED TO BY A SUFFERER FROM SLEEPLESSNESS.

"I own an empty palace in a strange country, said a congressman who suffers from insomnia the other day to a Washington *Star* reporter. "When I am trying to get sleep I visit it. It is a dismal edifice built in the form of a square and ever so many stories high, with but one entrance, at the front. A corridor runs all around it within, and inside the building there is a great open court, upon which every room looks out. There are forty rooms on each side of each story opening on the corridor. I make it my business at such times to inspect them. None of them are locked, because there is nothing to steal. I am obliged to examine all the rooms, and for this purpose I begin at No. 1 on the north-west corner, and follow the numbers along. Each door I come to I must open and after looking in must close it again. In this way I inspect each of the forty rooms on the west side. A brief look is sufficient because they are all precisely alike and have no furniture in them. Then I keep on along the south side, opening each door, looking in and shutting it in its turn. Thus I pursue my way around until I have finished with the eighty rooms on the first floor, arriving at the north-west corner again. At that corner is an elevator, conducted by the only living being in the edifice. He is deaf and dumb. He transports me to the second floor, where I inspect all the eighty rooms in the same fashion. It is monotonous work. They are all precisely like those below, none of them is occupied or has any furniture. Once in a while I enter one of the apartments, go to the single window at the further end and look out upon the court. It is empty. When I have finished the second floor the deaf and dumb man conveys me by the elevator to the third story. I do that in like manner, and after it the fourth and fifth, and so on. The task is a tiresome one. I have to keep the run of the number of the rooms, or else go back to the north-west corner on whatever floor I may happen to be and begin over again. There is an indefinite number of stories, so that sooner or later I am sure to fall asleep. In fact, I can get to sleep easier at that work than in any other way, and I recommend every one who suffers from insomnia to have a palace like mine in the land of nod with a deaf and dumb man to run the elevator."

TELEPHONIC RISKS.—Danzig officials have discovered that bacillary infections can be communicated by the "membranes" of telephones.

LIGHTNING CALCULATOR.—The earth is gradually growing larger from the fall of meteoric matter. An astronomer estimates that the globe is annually being pelted with 143 000,000 projectiles.

CUBIC WEALTH.—It has been estimated that the amount of gold in coin or ornament in the world is about 613 cubic yards, and that it would fit in a room 24 feet each way if in a solid cube.

DEVOURING LOVE.—The Shan Chinese, a people living between Burmah and China, show their love for their parents by killing them and eating them to save them from the misery of old age.

GOOD, IF TRUE.—A Frenchman has succeeded in making commercially pure chloroform. Heretofore this has been considered impossible. As the impurities in chloroform are generally the cause of fatal effects, the Frenchman's achievement is regarded as very important.

BRIGHT STORIES.

THE QUICK-BOY SAND.

(*Concluded from page* 461.)

When my senses returned, I became aware, first, that I was lying, bound hand and foot and securely gagged, upon the turf; secondly, that the horses were still tethered and standing quietly at the foot-bridge; and thirdly, that my companion had resumed his position on the bowlder, and there sat watching my recovery.

Seeing my eyes open, he raised his hat and addressed me in tones of grave punctilio.

"Believe me, sir. I am earnest in my regret for this state of things. Nothing but the severest necessity could have persuaded me to knock the son of my late esteemed friend over the skull and gag his utterance with a stone—to pass over the fact that it fairly lays my sense of your hospitality under suspicion. Upon my word, sir, it places me in a cursedly equivocal position!"

He took a pinch of snuff, absorbed it slowly, and pursued:

"It was necessary, however. You will partly grasp the situation when I tell you that my name is Teague—the Rev. William Teague, Doctor of Divinity, and formerly incumbent of Bleakirk-on-Sands."

His words explained much, though not everything. The circumstances which led to the Rev. William's departure from Bleakirk had happened some two years before my birth; but they were startling enough to supply talk in that dull fishing village for many a long day. In my nursery I had heard the tale that my companion's name recalled; and if till now I had felt humiliation, henceforth I felt absolute fear, for I knew that I had to deal with a madman.

"I perceive by your eyes, sir," he went on, "that with a part of my story you are already familiar; the rest I am about to tell you. It will be within your knowledge that late on a Sunday night, just twenty-nine years ago, my wife left the vicarage house, Bleakirk, and never returned; that subsequent inquiry yielded no trace of her flight, beyond the fact that she went provided with a small hand-bag containing a change of clothing; that, as we had lived together for twenty years in the entirest harmony, no reason could then, or afterwards, be given for her astonishing conduct. Moreover, you will be aware that its effect upon me was tragical; that my lively emotions underneath the shock deepened into a settled gloom; that my faculties (notoriously eminent) in a short time became clouded, nay, eclipsed—necessitating my removal (I will not refine) to a mad-house? Hey, is it not so?"

I nodded assent as well as I could. He paused, with a pinch between finger and thumb, to nod back to me. Though his eyes were now blazing with madness, his demeanor was formally, even affectedly, polite.

"My wife never came back; naturally, sir—for she was dead."

He shifted a little on the bowlders, slipped the snuff-box back into his waistcoat pocket, then, crossing his legs and clasping his hands over one knee, bent forward and regarded me fixedly.

"I murdered her," he said, slowly, and nodded.

A pause followed that seemed to last an hour. The stone which he had strapped in my mouth with his bandana was giving me acute pain; it obstructed, too, what little breathing my emotion left me, and I dared not take my eyes off him. The strain on my nerves grew so tense that I felt myself fainting, when his voice recalled me.

"I wonder now," he asked, as if it were a riddle—"I wonder if you can guess why the body was never found?"

Again there was an intolerable silence before he went on.

"Lydia was a dear creature; in many respects she made me an admirable wife. Her affection for me was canine—positively. But she was fat, sir; her face a jelly, her shoulders mountainous. Moreover, her voice!—it was my cruciation—monotonously, regularly, desperately voluble. If she talked of archangels, they became insignificant—and her themes, in ordinary, were of the pettiest. Her waist, sir, and my arm had once been commensurate; now not three of Homer's heroes could embrace her. Her voice could once touch my heart-strings into music; it brayed them now, between the millstones of the commonplace. Figure to yourself a man of my sensibility condemned to live on these terms!"

He paused, tightened his grasp on his knee, and pursued:

"You remember, sir, the story of the baker in Langius? He narrates that a certain woman conceived a violent desire to bite the naked shoulders of a baker who used to pass underneath her window with his wares. So imperative did this longing become, that at length the woman appealed to her husband, who (being a good-natured man and unwilling to disoblige her) hired the baker, for a certain price, to come and be bitten. The man allowed her two bites, but denied a third, being unable to contain himself for pain. The author goes on to relate that, for want of this third bite, she bore one dead child and two living. My own case," continued the Rev. William "was somewhat similar. Lydia's unrelieved babble reacted upon her bulk, and awoke in me an absorbing, fascinating desire to strike her. I longed to see her quiver. I fought against the feeling, stifled it, trod it down—it awoke again. It filled my thoughts, my dreams; it gnawed me like a vulture. A hundred times while she sat complacently turning her inane periods, I had to hug my fist to my breast, lest it should leap out and strike her senseless. Do I weary you? Let me proceed:

"That Sunday evening we sat, one on each side of the hearth, in the vicarage drawing-room. She was talking—talking; and I sat tapping my foot and whispering to myself, 'You are too fat, Lydia, you are too fat.' Her talk ran on the two sermons I had preached that day, the dresses of the congregation, the expense of living, the parish ailments—inexhaustible, trivial, relentless. Suddenly she looked up and our eyes met. Her voice trailed off and dropped like a bird wounded in full flight. She stood up and took a step toward me. 'Is anything the matter, William?' she asked, solicitously. 'You are too fat, my dear,' I answered, laughing, and struck her full in the face with my fist.

"She did not quiver much—not half enough—but dropped like a half-full sack onto the carpet. I caught up a candle and examined her. Her neck was dislocated. She was quite dead."

The madman skipped up from his bowlder and looked at me with indescribable cunning.

"I am so glad, sir," he said, "that you did not bleed when I struck you; it was a great mercy. The sight of blood affects me—ah!" he broke off with a subtle quiver and drew a long breath. "Do you know the sands by Woeful Ness—the Twin Brothers?" he asked.

I knew that dreary headland well. For half a mile beyond the gray church and vicarage of Bleakirk it extends, forming the northern arm of the small fishing-bay, and protecting it from the full set of the tides. Toward its end, it breaks away sharply, and terminates in a dorsal ridge of slate-colored rock that runs out for some two hundred feet between the sands we call the "Twin Brothers." Of these, that to the south and inside the bay is motionless, and bears the name of the "Dead-Boy;" but the "Quick-Boy," to the north, shifts continually. It is a quicksand, in short, and will swallow a man in three minutes.

"My mind," resumed my companion, "was soon made up. There is no murder, thought I, where there is no corpse. So I propped Lydia in the arm-chair, where she seemed as if napping, and went quietly upstairs. I packed a small handbag carefully with such clothes as she would need for a journey, descended with it, opened the door, went out to be sure the servants had blown out their lights, returned, and hoisting my wife on my shoulder, with the bag in my left hand, softly closed the door and stepped out into the night. In the shed beside the garden gate the gardener had left his wheelbarrow. I fetched it out, set Lydia on the top of it, and wheeled her off towards Woeful Ness. There was just the rim of a waning moon to light me, but I knew every inch of the way.

"For the greater part of it I had turf underfoot, but where this ended and the rock began I had to leave the barrow behind. It was ticklish work, climbing down; for footing had to be found, and Lydia was a monstrous weight. Pah! how fat she was and clumsy, lolling this way and that; besides, the bag hampered me. But I reached the foot at last, and, after a short rest, clambered out along the ridge as fast as I could. I was sick and tired of the business.

"Well, the rest was easy. Arrived at the furthest spit of rock I tossed the bag from me far into the northern sands. Then I turned to Lydia, whom I had set down for the moment In the moonlight her lips were parted as though she were still chattering; so I kissed her once, because I had loved her, and dropped her body over into the Quick-Boy Sand. In three minutes or so I had seen the last of her.

"I trundled home the barrow, mixed myself a glass of whiskey, sat beside it for half an hour, and then aroused the servants. I was cunning, sir, and no one could trace my footprints on the turf and rock of Woeful Ness. The missing handbag and the disarray I had been careful to make in the bedroom, provided them at once with a clew—but it did not lead them to the Quick-Boy. For two days they searched; at the end of that time it grew clear to them that grief was turning my brain. Your father, sir, was instant with his sympathy; at least ten times a day I had much ado to keep from laughing in his face. Finally two doctors visited me, and I was taken to a mad-house.

"I have remained within its walls twenty-nine years—but no, I have never been thoroughly at home there. Two days ago I discovered that the place was boring me, so I determined to escape; and this, to a man of my resources, presented few difficulties I borrowed this pony from a stable not many yards from the mad-house walls; he belongs, I think, to a chimney-sweep, and I trust that, after serving my purpose, he may find a way back to his master."

I suppose at this point he must have detected the question in my eyes, for he cried, sharply:

"You wish to know my purpose? It is simple." He passed a thin hand over his forehead. "I have been shut up, as I say, for twenty-nine years, and I now discover that the mad house bores me. If they retake me—and the hue and cry must be out long before this—I shall be dragged back. What, then, is my proposal? I ride to Bleakirk and out along the summit of Woeful Ness. There I dismount, turn my pony loose, and, descending along the ridge, step into the sand that swallowed Lydia. Simple, is it not? *Excessi, evasi, evanui.* I shall be there before sunset—which reminds me," he added, pulling out his watch, "that my time is nearly up. I regret to leave you in this plight, but you see how I am placed. I felt, when I saw you, a sudden desire to unbosom myself of a secret, which, until the past half hour, I have shared with no man. I see by your eyes again that if set at liberty you would interfere with my purpose. It is unfortunate that scarcely a soul ever rides this way—I know the road of old. But to-morrow is Sunday; I will scribble a line and fix it on the church door at Bleakirk, so that the parish may, at least, know your predicament before twenty-four hours are out. I must

now be going. The bandana about your mouth I entreat you to accept as a memento. With renewed apologies, sir, I wish you good day; and count it extremely fortunate that you did not bleed."

He nodded in the friendliest manner, turned on his heel, and walked quietly toward the bridge. As he untethered his pony, mounted, and ambled quietly off in the direction of the coast, I lay stupidly watching him. His black coat for some time lay, a diminishing blot, on the brown of the moors, stood for a brief moment on the sky line, and vanished.

I must have lain above an hour in this absurd and painful position, wrestling with my bonds and speculating on my chances of passing the night by the beck side. My ankles were tied with my own handkerchief, my wrists with the thong of my own whip, and this especially cut me. It was knotted immovably; but, by rolling over and over and rubbing my face into the turf, I contrived at length to slip the gag down below my chin. This done, I sat up and shouted lustily.

For a long time there was no reply but the whinnying of my mare, who seemed to guess something was wrong, and pulled at her tether until I thought she would break away. I think I called a score of times before I heard an answering "Whoo-oop!" far back on the road, and a scarlet coat, then another, and finally a dozen or more appeared on the crest of the hill. It was the hunt returning.

They saw me at once, and galloped up, speechless from sheer amazement. I believe my hands were loosened before a word was spoken. The situation was painfully ridiculous; but my story was partly out before they had time to laugh, and the rest of it was gasped to the accompaniment of pounding hoofs and cracking whips.

Never did the Netherkirk Hunt ride after fox as it rode after the Rev. William Teague that afternoon. We streamed over the moor, a thin, red wave, like a rank of charging cavalry, the whip even forgetting his tired hounds that straggled aimlessly in our wake. On the hill above Bleakirk we saw that the tide was out, and our company divided without drawing rein, some four horsemen descending to the beach, to ride along the sands out under Woeful Ness and across the Dead Boy, hoping to gain the ridge before the madman and cut him off. The rest, whom I led by a few yards, breasted the height above and thundered past the gray churchyard wall. Inside it I caught a flying glimpse of the yellow pony quietly cropping among the tombs. We had our prey, then, inclosed in that peninsula as in a trap; but there was one outlet.

I remember looking down toward the village as we tore along, and seeing the fisher-folk run out of their doors and stand staring at the two bodies of horsemen thus rushing to the sea. The riders on the beach had a slight lead of us at first; but this they quickly lost as their horses began to be distressed in the heavy sand. I looked back for an instant. The others were close at my heels; and, behind again, the bewildered hounds followed, yelping mournfully. But neither man nor hound could see him they hunted, for the cliff's edge hid the quicksand in front.

Presently the turf ceased. Dismounting, I ran to the edge and plunged down the rocky face. I had descended about twenty feet, when I came to the spot where, by craning forward, I could catch sight of the spit of rock and the Quick-Boy Sand to the right of it.

The sun—a b'azing ball of red—was just now setting behind us, and its level rays fell full upon the man we were chasing. He stood on the very edge of the rocks, a black spot against the luminous yellow of sea and sand. He seemed to be meditating. His back was toward us, and he perceived neither his pursuers above nor the heads that, at this moment, appeared over the ridge behind him and not fifteen yards away. The party on the beach had dismounted and were clambering up stealthily. Five sceonds more and they could spring upon him.

But they under-estimated a madman's instinct. As if for no reason, he gave a quick start, turned, and, at the same instant, was aware of both attacking parties. A last gleam of sunlight fell on the snuff-box in his left hand; his right thumb and forefinger hung arrested, grasping the pinch. For fully half a minute nothing happened; hunters and hunted eyed each other and waited. Then, carrying the snuff to his nose and doffing his hat with a satirical sweep of the hand and a low bow, he turned again and tripped off the ledge into the jaws of the Quick-Boy.

There was no help now. At his third step, the sand had him by the ankles. For a moment he fought it, then, throwing up his arms, sank forward, slowly and as if bowing yet, upon his face. Second by second we stood and watched him disappear. Within five minutes the riples of the Quick-Boy Sand met once more above him.

In the course of the next afternoon, the Vicar of Bleakirk called at the hall with a paper which he had found pinned to his church door. It was evidently a scrap torn from an old letter, and bore, scribbled in pencil by a clerkly hand, these words: "The young Squire Cartwright in straits by the foot-bridge, six miles toward Netherkirk. *Orate pro anima Gulielmi Teague.*"

AN ADULTERATION ADVOCATE.

ONE WORD FOR THE PUBLIC AND TWO FOR THE SWINDLER.

The *Journal of Commerce* recently received from an anonymous pen a communication which it is pleased to characterize as a "most elaborate defense" of adulteration. From our contemporary's description of the document in question, we should be inclined to regard it as a very flimsy "defense." Our contemporary, after some introductory remarks, says: This writer defends adulterations of every description as altogether in the public interest. Animal fat, digested with a pig's stomach, flavored with a little cream and colored to suit, is just as good, he claims, as butter, if not really better, and can be sold for but little more than half the price of the genuine article. Salad oil made from cottonseed or peanuts can be produced at a much lower cost than that which is pressed from the olive nut, and is every way more desirable. Lard which is only half the product of the pig will maintain its consistency much better by the addition of the vegetable oil, and this discovery is a great boon to the consumer. It suggests that it may be better still if none of its contents come from the defunct swine. In spices the gain to the public health, according to his new creed, is enormous. Pepper and mustard irritate the stomach, and the mild articles used in adulteration diminish the evil. Allspice and cinnamon are ground with adulterants quite as agreeable to the palate and far more healthful. We suppose that if the wooden nutmegs for which Connecticut has been so persistently chaffed could be utilized without injury to the grater, the substitute would also be commended. It is well known that one reason why the physicians of our day have so largely curtailed the administration of remedies is the the fact that but few drugs now on the market are pure, or can be had in their natural condition. This, of course, is used by the defender of adulterations as another reason why there should be no mourning over such mixtures. Anything which will keep the doctors from dosing their patients on the old heroic plan is a blessing, however disguised. The same argument he applies to the adulterations of liquor and wines. His arguments here are a little inconsistent. He contends, first, that the mixtures sold for brandy and the like, or passed off as port, sherry or champagne, are far less likely to injure the system than the genuine product of the distillery or the wine vat; and further that the discovery of such adulterations has done a vast work for the cause of temperance by deterring consumers from the use of these beverages. It would seem that if the adulteration produced an article equal in flavor to the genuine product and less injurious to the health, the dram-drinker or the wine-bibber would not feel the force of the last-named arguments and restrict his potations. Besides, it is our impression that the artificial brandies and wines are not as innocuous as insisted on, and that the concoction is not in the interest of the public health. A similar argument is applied to the manipulation of tea and coffee. The defender of the fraudulent mixture insists that both of these beverages are injurious to man's physical system. Hence the rogue who dries out and redresses tea that has once been used, is saving the human stomach from an injury that might be fatal. And the use of dried and powdered bread, chicory, split peas, and a score of other things that are substituted for the coffee bean is to be commended on similar grounds. We notice that the London *Times* of August 19. calls attention to the novel manufacture on this side of the Atlantic of a substitute for coffee, noticed by us some time since, and which seems more recently to have found a market abroad. The production is not difficult. A compound of rye flour and glucose with a little water, thoroughly mixed and pressed in a mould, makes a berry which not even an expert can distinguish by sight from the genuine article. When ground coffee is sold, anything can be substituted for the berry whose name it bears; but when people become suspicious, and insist on grinding the product for themselves, the adulteration was a little more difficult. The artificial berries now answer all the purpose, and the fraud passes unnoticed. The motives of those who prepare these mixed and artificial products are also freed from reproach, as far as that can be done by this apologist for deception. He contends that as long as people were willing to pay for the genuine articles, the dealers sold them, and that the demand for something cheaper, even if it should be spurious, came from the consumer. We do not credit this statement. The adulterations came from greed. It is true that when one dealer inaugurated the fraud, his competitor felt compelled, as he would argue, to follow the example so as not to lose his customers. This is carrying out in practice the advertising witticism of the two broom merchants, one of whom announced that he could undersell all other dealers because he stole the raw material, while his rival the next day published an answering notice saying he could beat that, for he stole his brooms ready made. One man sells an article at a cheap price because it is only two-thirds genuine, and his competitor defeats the scheme by selling a substitute that is wholly artificial. There is no better field of adventure to day than a return to honest dealing, but it would be a herculean if not impossible task for a dealer to stock up with an assortment every item of which could be certified as genuine.

USEFUL MEASUREMENTS.—Cut this out and keep it handy for ready reference. A rod is 16½ feet, or 5½ yards; a mile is 320 rods; a mile is 1,760 yards; a mile is 5,280 feet; a square foot is 144 square inches; a square yard contains 9 square feet; a square road is 272¼ square feet; an acre contains 43,560 square feet; an acre contains 4,480 square yards; an acre contains 160 square rods; a section or square mile contains 640 acres; a quarter section contains 160 acres; an acre is 8 rods wide by 20 rods long; an acre is 10 rods wide by 16 rods long; an acre is about 208¾ feet square.

SLOW PROGRESS.—According to the census completed in August, the Dominion of Canada has a total population of 4,823,344, against 4,324,810 in 1881, a gain of 498,534, or 11½ per cent. in ten years. During the decade between 1881 and 1891 the Dominion received 886,171 immigrants, and the natural increase by births during the decade was 648,720, making a total increase of 1,534,891, while the census shows an increase of only 498,534. The balance, 1,036,357, represents the Canadians who have left the Dominion in ten years, most of whom have settled in the United States.

NEW YORK HOMES.

A CITY RESIDENCE THAT IS ALTOGETHER UNIQUE IN ITS BEAUTY.

There is a house not far from the Windsor Hotel which is a delight to the artistic sense, and a haven of rest after a round of afternoon calls. when eyes and brain are wearied to desperation by the endless perspective of long parlors and square dining-rooms with pictures along the walls, and tables and chairs at intervals along the floors, so characteristic of average New York dwellings. On the outside there is nothing to distinguish this house from its neighbors, except that the stone balustrade of the stoop has been exchanged for a graceful iron railing, and a single heavy iron-barred oak door closes the entrance. In answer to a ring this door opens slowly, and one stands in a square vestibule, lighted from above by queer Eastern lamps. A dark heavy curtain veils the stairway, and another to the left is drawn half back, inviting one to enter. Following the invitation, one stands in a little anteroom, shut off from the parlor by a screen. This room is dark in coloring, the windows are hung with rich draperies, and between them stands a high antique cabinet. Opposite the door is a great divan, piled high with cushions, and above it hangs a trophy of Oriental armor. A quaint little stool is before the sofa, just handy to sit on while examining the pile of photographs, the work of the mistress of the house, that lie ready at your hand. Going around the screen you find yourself in the main room, a luxuriously furnished library. Bookcases line two sides of it. The walls are a dull Indian red, easy chairs and divans stand anywhere and everywhere, a large library table with gold fittings fills one corner, and the whole is lighted by tall lamps with silk shades. A wood fire in the large open fireplace adds to the attractions of the room, and the perfume of incense burning in some of the many odd Eastern vases scattered about steals over your senses, and invites you to linger in this blest abode, where care seems unknown. It is essentially a "livable" room; books, papers, photographs are scattered about in apparent confusion, and nowhere is there a trace of stiffness or conventionally. Between the curtains closing the entrance to the room beyond falls a soft yellow light, and every now and then you hear a little musical tinkle, a snatch of aerial melody, that attracts your attention, and makes you wonder whence it comes. So you leave the luxurious library, and, parting the curtains, you walk through into the fairy-land beyond. At first you are conscious of nothing but the flood of yellow radiance that envelops you in its glory—dazzles and entrances you. Finally, you become aware that the whole room is cream-tinted, and that you are standing in just such an apartment as might have sheltered a belle of old Pompeii. Walls and ceiling are of palest cream, with festoons of roses in Pompeian pink, held up by queer figures, reproductions of ancient masks. The curtains are of lustreless silk of the same pale shade, and all the woodwork is like old ivory. In the corners stand four tall Roman lamps, each with four burners, and it is this steady blaze of unshaded gas, equally distributed, that gives the mellow yet intense radiance that fills the room. There is very little furniture here, a long sofa of antique design in wood like polished ivory, a cabinet and single chair of the same make, and two pianos—a grand and an upright, with stools and racks of white wood—are all you can see. Both instruments are open, and a glance at the music lying loose upon them is sufficient to show the musical creed of the hostess: opera scores, "Meistersinger, "Tristan," "Parsifal"—arrangements for two pianos, for pianos and violin, and so on *ad libitum*. Beethoven, Lizst and Chopin are also represented here, but undisputed lord of these domains is the Master of Bayreuth, whose strong face looks down from the top of the tall cabinet in the corner. On the upright stands a bust of Lizst, and on the mantel is a clock flanked by two vases, beautiful French work in black and gold, made from old Roman designs. Around the dial of the clock is a ring of Rhinestones, which makes a moving bit of brilliancy as it swings slowly back and forth. Again that musical tinkle, this time immediately behind you. You turn and see a door, on which hangs a queer shaped harp. Across the strings fall several wires, tipped with silver balls, and when the door is opened the balls strike the strings, producing a witching little melody. Behind this music room, one of the most beautiful of its kind in the city, comes the dining-room, which we cannot fail to admire, even after what we have just seen. It is an "early English" poem. The large, square window is all lozenge panes, as are the doors in the tall dresser, and the knobs on the doors are finished with miniatures on porcelain, buttons worn by gallants of earlier days, and collected by the lady of the house in her travels. Around the wall runs a frieze of priceless plates, gathered all over the world, and a great iron-bound antique linen chest fills you with admiration and envy, if you are antiquarian enough to appreciate its value. The upper floors are handsomely and tastefully furnished, but they are no different from what might be found in other wealthy homes, and cannot be compared in originality of beauty to the rooms below.—*Recorder.*

THE PRIMEVAL HORSE.

PREHISTORIC MAN AND THE HORSE IN NORTH AMERICA.

The genealogy of the horse has been most admirably worked out in various publications, and the fact has long been established that the genus originated on the North American continent. The question, however, as to whether prehistoric man in America had the horse as a contemporary has been a disputed point. This question may now be considered set at rest by the discovery of a skull of an extinct species of horse in strata with human implements. This discovery was announced by Prof. E. D. Cope, at the meeting of the American Association for the Advancement of Science, held in Washington in the month of August. A skull of a horse was exhibited to the members by Prof. Cope, who pointed out the characters of the teeth and who stated it would be impossible for any one to separate the fossil teeth from those of the quagga and zebra if the three were all thrown together. In minor characters, such as those of the size of the bones, the differences are perceptible. So there is no doubt the skull represents an animal different from any now living. That it was a horse, however, any one could see. The most curious thing about the skull was its condition. The frontal bone had been crushed in exactly as we see in the case of animals slaughtered for food. The friable bones protecting the eye sockets were intact, as were also the long nasal bones. Found in the same bed with the skull was a stone hammer that bore evident marks of having been fashioned by the hand of man. What inference was to be drawn from this? In the first place it has been suspected and considered probable that early man on this continent had been contemporaneous with a horse, though not the present living species, but no direct proof had hitherto been found. When Europeans landed on the new continent, the horse was an unknown animal to the natives. So it had evidently long been extinct. All the horses now found in either North or South America came from stock originally brought over by Europeans. But here we had evidence in the association of a human implement and a horse's skull that man and horse had lived together; and the peculiar fracture of the skull of the latter leads to the belief that the animal had met its death at the hands of man. This fact opens several questions. What became of the race of horses that once lived on the continent? Were they exterminated by savage man as civilized man has exterminated the bison? Did they once serve as beasts of burden or were they used only as food? Were they wild or domesticated? It seems probable that they were not used for any other purpose than as food, and that they existed only in a wild state, for it is scarcely reasonable to suppose that having once been used by man and so domesticated, their use would ever have been forgotten or the breed allowed to die out. Neither is it probable that they were exterminated solely by the agency of contemporaneous man, for we know that in spite of the use of the bison by the Indians of North America, their numbers did not decrease to any great extent. It was only when civilized (?) man began his destructive work that the bison began to disappear. What, then, was the cause of the disappearance of the horse? The age of the beds in which the remains are found is prior to the Ice Age that once prevailed in North America, and in this period of cold it is possible we have a factor to account for the extinction of the horse. The intense cold coming on forced the animals to migrate from their homes in the northwest of the United States, and retreating southward, they probably found many competitors for existence. The scanty vegetation of New Mexico, Arizona, and Northern Mexico probably did not suffice for the support of the great herds of animals coming from the north. New conditions of existence may have weakened the vitality of the species; starvation may have decimated their numbers; competition with other races must have cut off a large supply of food, and the hand of man may have hastened the struggle to its inevitable end. All we know, however, is that the race became extinct. That man lived previous to and of course during the Ice Age is now well established. That he lived at the same time with a species of horse if made known by the discovery of Prof. Cope. His influence in the extermination of many of the large mammals at one time inhabiting North America is as yet undetermined.—*Prof. Joseph F. James in Scientific American.*

GHOSTS AND VISIONS.

HYSTERIA A POTENT ALLY OF SUPERSTITION.

Excited nerves are one of the most annoying and most productive agencies for the breeding of unnecessary misery in the world. Most of us, probably, have had periods when vitality is at its ebb, and found a load on our shoulders which weighed upon both mind and spirits, with a sense of worry, a horror of other people's meddling, a feeling of self-mistrust, or the doom of some great evil upon our horizon. We conjure up visions of long forgotten blunders, and dwell upon them until they grow from mole hills into mountains; then the mistakes of yesterday—the sentences said or left unsaid, the deeds done or left undone—and there must be explanations and reversions immediately. Fortunately, with the bright cheerfulness of the sunshine, with the busy activity of the occupied life, comes the calming memory that we are morbid, possibly dyspeptic; that for a short period our nerves have been painfully excited, and, the predisposing cause being removed, the normal condition again prevails, and we are at peace. But there are people so constituted that their entire lives are passed in this febrile condition; and such a condition of mind may be classed as one of the misfortunes of life. It breaks up all the peace of domestic life, and wrecks the happiness and fortunes of many. Very trying such people are; they are not at peace themselves, and they are pre-determined not to let others enjoy any quiet which they have the power to destroy. These spells of morbid fancies and unbid depressions visit men and women alike, so far as we can judge; but in all literatures and times past, when it comes to pure, unreasoning worrying, active suffering, selfish teasing, women have been given the preëminence. Not that all women, or any considera-

ble number of women, suffer in this manner, but a certain hysterical temperament is subject to such fits. Considering the predisposing causes, it would seem that the controlling power, which could check such a state in its earlier stages, at least, is more at fault than the active agent. A yielding and uxurious husband is commonly the foil for breeding this sort of tyranny. The nervous fancies should be controlled, and, when beyond the patient's power, to have some one who should be master, but is not, allows the disorders to grow to undue proportions. As an instance, Queen Constance, who, by her great griefs, and without controlling power of any kind, became heroic in her selfish agony, has made herself the type of this form of hysteria. Self was the center of all her wailings, not Arthur's unhappiness. It is to nerves so painfully excited and imagination so diseased that the outgrowth of ghosts and superstitious visitations is, undoubtedly, often due. In this state of mind and after some severe nervous shocks — as the loss of some near friend — the latent ideas entertained by the individual as to spiritual agencies, ghosts, and visions have much to do with such phenomena. To a believer in ghosts, any apparition, sound, or startling coincidence will be accredited with a supernatural origin in the mind of the observer, and he usually accepts the data as a fact, and makes no inquiries which might enlighten him on the purely natural cause for the phenomenon. There was an instance which seemed to be attested by so many persons, that it was difficult to believe so many could be subject to a delusion in the matter. An artist was sketching on one of the bold promontories of the many fantastically shaped mounds in south-eastern Kansas, and late in the evening descended to the valley to find several families in a state of nervous excitement, each person testifying to the warning given by the appearance of a ghost. It appeared and disappeared above the the outline of the ridge of the high mound where the artist had been working for hours. A great billowy object, resembling the distended skirts of a woman, had been seen to rise above the horizon, and then to sink down and disappear, only to show itself at some other point—now higher up nearer the summit of the mound, and then away down the side. The fact that the object sank down clear out of sight and then reappeared, only caused the greater excitement. It was thought to be the ghost of an early settler, who had been murdered during the border troubles of the early settling of the State; and, as her grave was on the highest point on the mound, it was prophesied that she had visited the scene of her earthly suffering to give warning to those now living near the site of some pending disaster. Under the conditions, excitement ran high: and it was noticeable that most of those present were prepared to be deceived, and more than one was vibrating in nervous tremors, and occupied the time in relating stories of second sight, goblins, and ghosts. One of the company, the unmarried sister of the hostess, who was quite ill, had an attack of hysteria, and the prolonged shrieks sounded lugubrious and added to the predisposition to expect something horrible. The house stilled down, however, and when the cheerful sunshine of a brilliant July day awakened all to a state of healthy, happy activity, it seemed quite improbable that anything supernatural would show itself. But the early breeze, which usually begins to blow soon after sunrise and increases in intensity as the day grows warmer, seemed to stir the ghost from its haunts. Peter, the ploughman, who, after breakfast, had gone happily to his work, forgetful of the tremors of yesterday, came to the house with a blanched face, bringing his team, protesting against being in the field when "that thar ghost war on the rise." The poor hysterical patient was again in agony, and the artist, finding no one else equal to the task of investigation, started for the mound. Her white canvas umbrella, which had been staked on the top of the bluff for some days, had escaped its fastenings, but was held by the cord tied at the outer edge and secured to a stake to steady it in high winds. It had been swept to and fro by the breeze, and its gyrations could be seen from the valley. So the ghost was laid, but not the hysteria. In the mining regions of Missouri there was at one time an epidemic of fits, originating in a religious excitement where many converts were violently agitated, and, after hours of violent excitation, became stiff and stark, lying in a trance state. The report grew that a certain large oak tree, standing at the fountain-head of Roaring river, was burning, although no flame was to be seen, but great columns of smoke ascended from the green boughs during certain hours of the day. Soon many invalids were attracted, and, as there was no visible cause for fire, great wonder fell upon them. And the excitement grew and the frenzy prevailed, until one bold investigator climbed to the topmost branch. The enigma was solved. Innumerable myriads of gnats were swarming, and, as they disported themselves in the sunshine, the great spirals and clouds of smoke, black and rushing, seemed to issue from the tree. The great emotional wave, however, had its full tide. Of the many indefinite distresses to which human nature is subject, there is none more real than that aroused by unexplained natural phenomena and the consequent fright. The result is known by many names: nerves, spleen, vapors, megrims, ennui, and last and most expressive name, because always applicable—hysteria.—*Pop. Science News.*

DOMESTIC DIETETICS.

SPECIALLY PREPARED, FROM PRACTICAL TESTS, FOR THE LADY READERS OF THE "AMERICAN ANALYST."

SEASONABLE FOOD.

October.

MEATS.—Beef, mutton, ham, kidneys, liver, venison, sausage.

GAME AND POULTRY.—Pigeon, chicken, duck, woodcock, brant, grouse, partridge, rabbit, snipe, goose.

FISH.—Bass, blackfish, bluefish, clams, cod, crabs, eels, carp, catfish, flounder, halibut, herrings, lobster, mackerel, mussels, oysters, pike, porgie, prawn, rockfish, salmon, sea bass, sturgeon, smelt, turtle, white fish, whiting.

VEGETABLES.—Artichokes, beets, beans, broccoli, Brussels sprouts, cabbage, carrots, cauliflower, corn, cucumbers, egg-plant, garlic, lettuce, onions, parsley, parsnips, potatoes, radishes, rhubarb, savoy, shallots, spinach, squash, tomatoes, turnips, watercress.

FRUITS.—Apples, bananas, blackberries, grapes, melons, oranges, peaches, pears, pineapples.

PRACTICAL RECIPES.

BAKED POTATOES.—Select medium sized potatoes and wash them carefully, butter the skin all over, lay them in a pan and bake in a hot oven. They should come from the oven a very delicate brown.

LOBSTER MAYONNAISE SANDWICH.—Boil your lobster and pick or chop it up very fine, make a rich mayonnaise dressing and mix the lobster with it and put it between layers of bread.

SARDINE SANDWICHES.—Drain the oil from a box of sardines and lay them on soft paper to absorb the oil, remove the bones and chop the fish up very fine, add to them the juice of a small lemon, a dessert spoonful of melted butter, a little cayenne pepper and salt, mix very thoroughly together. Spread this paste on a thin slice of bread, and put another slice on top.

TO PRESERVE LEMONS.—Varnish them with a solution of shallac in spirits of wine, and they will keep fresh a long time.

ALMOND PASTE.—Scald your almonds and remove the skin and pound them well in a mortar until they are fine, moistening them frequently with the white of an egg whipped up with orange flower water, which will keep them from turning to oil. When the paste is very smooth spread it out on a dish and dry it with fine sugar until it becomes pliable. Let it lie a while before using.

COFFEE CAKE.—Four eggs, two cupfuls sugar, one cupful butter, one cupful molasses, five cupfuls flour, one cupful very strong coffee, one teaspoonful cinnamon, one teaspoonful cloves, one nutmeg, one very scant teaspoonful soda, two cupfuls boiled cider or one cupful mild vinegar sweetened, one pound stoned raisins.

WALNUT CAKE.—One and one-half cupfuls sugar, one and one-half cupfuls butter, two-third cupfuls sweet milk, whites four eggs, two cupfuls flour, two teaspoonfuls baking powder, two-third cupful walnuts, two-third cupfuls raisins.

HICKORY NUT CAKES.—Two third cupfuls butter, two cupfuls sugar, two and one-half cupfuls flour, one cupful sweet milk, one teaspoonful baking powder, four eggs, two cupfuls hickory nut meats. Paper your pans and drop the batter on with a table-spoon forming small round cakes.

CHESS PIE.—Three eggs, two-third cupful sugar, one half cupful butter. Beat butter to a cream, add yolks and sugar beaten to a froth with a little vanilla. Stir all together and bake in one crust. When done spread with the beaten whites and three table-spoonfuls of sugar and a little flavoring. Return to oven and brown. Serve immediately.

CHARACTERISTICS OF PLANETS.—Mercury is the nearest to the sun. Venus is almost the same size as the earth and rotates on her axis in nearly the same number of hours. Mars is smaller than the earth, has two moons and is most like it as regards possibilities of habitation; water and land are equally divided on Mars, and the poles of the planet are icebound. Jupiter, the giant planet, is 1,230 times as large as the earth and has four moons. Saturn has a gorgeous system of rings which completely surround it, and in this respect is unlike any other planet. Uranus is seventy-four times as large as the earth and has four moons. Neptune has one moon, is 105 times as large as the earth and is the furthest planet from the sun yet discovered.

ELECTRIFIED ICE CREAM.—A new experience of the danger of electricity has to be recorded. Dr George S Hull recently conducted some experiments with ice-cream freezers, and he finds that galvanic action takes place, which results in the introduction of poisonous salts of copper and zinc into the cream. It appears that the freezer and the paddle are generally made of dissimilar metals, and the cream, especially if mixed with fruit or other acid, or even saline substances, forms an electrolyte, which naturally completes the necessary conditions for galvanic action. With galvanic action there is, of course, chemical action, resulting in the formation of salts of zinc and copper, which become mixed with the cream. Dr. Hull has probably discovered the cause of many mysterious cases of poisoning which have followed the consumption of ice cream. The remedy, however, seems very simple; if the freezer and the mixer were made of the same metal, no galvanic action could take place.

DESIRABLE DEVICE.—A common source of cold and discomfort in winter is the draught from the bottom of a shrunken or badly fitting door. A device has been brought out by which these currents of air can be so diverted as to be made desirable instead of objectionable. A slab of wood works on two pivot hooks projecting from the bottom of the door, and fitted at one end with a curved piece of wood, which comes against the jamb on closing the door and presses a felt-facing close to the door. On opening the door an India rubber spring draws the bottom of the slab toward the door, and so clears the carpet. The bottom edge of the slab, being lined with felt, is absolutely draught-tight. On the door being shut the air which rushes in strikes against the slab, is turned upward, and goes to the top of the room. In this way the draught under the door, which was before a constant menace to the health of the occupants of the room, becomes a positive advantage in promoting the thorough ventilation of the apartment.

BUSINESS NOTES.

HORSFORD'S ACID PHOSPHATE.

A brain and nerve food, for lecturers, teachers, students, clergymen, lawyers, and brain-workers generally. Dr. I. R. Sanford, Sheffield, Mass., says: "Most excellent in derangements of the nervous system, such as headache and sleeplessness."

A RISING WESTERN CITY.

PART 2.

But it must not be forgotten that Watertown is already a city of the finest buildings in the State, a city of great wealth and prosperity, a city of manufacturing institutions, wholesale houses, motor lines, lighted by gas and electric lights, a city of beautiful residences, churches, streets, parks, avenues and drives, magnificent school buildings, hotels and mercantile houses. A banquet was given on the 18th of last June to a delegation of New England gentlemen by the citizens of Watertown, and the address of welcome was delivered by Hon. E. C. Mellette, Governor of South Dakota. The Governor's speech was replied to by one of the party, who took for his toast, "The Three Dakotas—the Past, Present and Future." The following extracts from his speech will give the reader an idea of the Wealth of this New World. Governor Mellette, Ladies and Gentlemen: "I poorly express the feelings of my associates and myself when I say that we are glad to meet in these splendid Dakotas so many prosperous and happy men and women. * * * Think for a moment what you have: South Dakota, geographically speaking, is an empire herself, her head in the Rockies, jeweled and bedecked in ice and snow, her feet in the rich warm valley of the Sioux adorned with summer harvests and fragrant with prairie roses South Dakota is a country capable of producing from her soil everything necessary for the comfort and blessing of human life. Twelve years ago a population of 30,000 inhabitants, and most of these tenting on the plains, to-day a population of 450,000 men, women and children in comfortable homes, surrounded by plenty, happy, contented, and growing rich. Thirteen years ago not a white man within 125 miles of where I stand; to-day a beautiful city, rising, as by magic, from the lap of your lakes, and from your virgin and verdant soil. Think of it, the infant State of America yielding 22,000,000 bushels in wheat, 10,000,000 bushels of oats, 4,000,000 of barley; 5,000,000 of flaxseed, 25,000,000 bushels of corn, 3 000,000 bushels of potatoes, lesser vegetables in proportion, 10,000,000 pounds of wool, 5,000,000 head of horses, cattle, sheep and hogs. The indications now are that your harvests this year will be double what they ever have been. The picture is nothing less than a transformation scene, yesterday a wild prairie roamed over by the Indian and the coyote, to-day a rich and prosperous field inhabited by the best civilization of the western world. You have a great system of railways, and to reproduce them would cost upward of $210,000,000. You are connected directly by your railroads, with Duluth on the north, Minneapolis and St Paul on the east, Chicago southeast, Omaha south, the sheep prairies of Wyoming southwest. Bismarck, the Northern Pacific, with its tributaries northwest, and the Black Hills, the centre of American tin and the centre of many of the largest gold and silver mines in the country, in the West. So peculiar is your railroad competition that you can ship your products to the eastern States and Europe as cheap as they can be shipped from Minneapolis, though you are 226 miles west of Minneapolis. When such great railroad corporations as the Chicago and Northwestern, the Rock Island, the Minneapolis, Manitoba & Northern, kings of travel and trade, pounce down upon your town, it means that you have something worth having; it means that you are to have a city which will direct the trade of the Northwest, a city of mills and factories sufficient to take care of your grain and fibre—woollen mills for your wool, linen mills for your flax, strawboard mills for the million tons of straw you annually waste; shoe factories for your hides, starch factories for your potatoes, sugar mills for your beets; it means mills to manufacture the products you grow as you grow them, instead of freighting them 2,000 miles east to be manufactured and then shipping the manufactured goods back to you. Why should not Watertown become a great city? Your climate alone should induce thousands to visit your city every summer and autumn; your lakes, your fields and landscapes, thousands more. Statistics show that where the death rate throughout the United States is 160, the death rate in South Dakota is but 66. No pestilence or scourge has ever visited your fair shores, nor has malaria, the curse of many western and southern States, ever by its poisonous breath, affected one of your homes—a country of vigor in its brain, health in its bosom, and energy at its feet. In a word, South Dakota is the most healthy northern climate on this continent." * * * * * * The boom has struck the city; people are arriving on every train from all sections of the world; work is progressing of every nature, and here and there streets and parks are being made. I understand an excursion will leave Boston, September 29, for this city, under the auspices of Raymond & Whitcomb. This will be a great opportunity for New Englanders to visit this land of wealth and beauty, of golden sun and Indian summer—the most beautiful country in the great Northwest. South Dakota will sell upwards of $100,000,000 of produce this year, While writing from the observatory on Capital Hill, I see five trains departing and four arriving; I see thousands of stacks of grain in all directions, and long lines of wagons over nine roads, hauling the products of the season; I hear the sportsman's gun as he pursues the trail of the wild chicken; the motor cars are filled with excursionists, picnicking on the shores of the lake; I can see for forty miles in every direction, and as far as the eye can reach is a great harvest of wealth. The finest hotel in the State is the Arcade Hotel, the finest business block the Granite block, the finest school building the High School, all of Watertown. There are more pretty women in Watertown than I have ever seen in any town of its size, except Paris, Ky. It is a city of schools and churches, and educational attainments rank high.—*Boston Herald.*

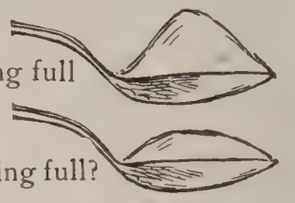
A Tonic

Horsford's Acid Phosphate.

A most excellant and agreeable tonic and appetizer. It nourishes and invigorates the tired brain and body, imparts renewed energy and vitality, and enlivens the functions.

Dr. EPHRAIM BATEMAN, Cedarville, N. J., sasy:

"I have used it for several years, not only in my practice, but in my own individual case, and consider it under all circumstances one of the best nerve tonics that we possess. For mental exhaustion or overwork it gives renewed strength and vigor to the entire system."



Descriptive pamphlet free.

Rumford Chemical Works, Providence, R. I.

Beware of Substitutes and Imitations.

CAUTION:—Be sure the word "Horsford's" is on the label. All others are spurious. Never sold in bulk.

Is a spoonful a spoon

heaping full

or

rounding full?

One rounded teaspoonful of Cleveland's Baking Powder does as much work as a heaping teaspoonful of others; quite a saving on a year's bakings.

Cleveland's leavens *most* and leavens best. Try it.

EVERY one in need of information on the subject of advertising will do well to obtain a copy of "Book for Advertisers," 368 pages, price one dollar. Mailed, postage paid, on receipt of price. Contains a careful compilation from the American Newspaper Directory of all the best papers and class journals; gives the circulation rating of every one, and a good deal of information about rates and other matters pertaining to the business of advertising. Address

ROWELL'S ADVERTISING BUREAU,

PURE PEPSIN

In Powder and Scale.

MANUFACTURED BY

ARMOUR & COMPANY, Chicago.

Guaranteed free from adulteration or make-weights; of excellent physical properties and high digestive power.

Under similar conditions, **ARMOUR'S PEPSIN** will exhibit greater activity than any other pepsin now before the profession.

The Manufacturers will be pleased to supply members of the Medical Profession with samples of their Pepsin, and with full details regarding digestive strength, if desired.

GOLD MEDAL, PARIS, 1878.

W. BAKER & Co.'s Breakfast Cocoa

from which the excess of oil has been removed,

Is Absolutely Pure and it is Soluble.

No Chemicals

are used in its preparation. It has *more than three times the strength* of Cocoa mixed with Starch, Arrowroot or Sugar, and is therefore far more economical, *costing less than one cent a cup.* It is delicious, nourishing, strengthening, EASILY DIGESTED, and admirably adapted for invalids as well as for persons in health.

Sold by Grocers everywhere.

W. BAKER & CO., DORCHESTER, MASS.

HAMMOND'S

CELEBRATED

Calumet Oleomargarine

Strictly pure, cheap and healthful.

Ask your grocer for it.

Put up in packages of all sizes, also prints and rolls.

C. H. HAMMOND CO.,

607 to 615 THE ROOKERY,

CHICAGO.

Also offices at Boston, South Omaha, Neb., and Hammond, Ind.

WATERTOWN, South Dakota.

A NATURAL centre and distributing point. The following extracts from a response to an address of welcome from Governor Millette, of South Dakota, to a party of Boston business men, presents a vivid picture of the resources of South Dakota, and the future of its destined capital.

"South Dakota, geographically speaking, is an empire herself, her head in the Rockies, jewelled and bedecked in ice and snow, her feet in the rich, warm valley of the Sioux, adorned with summer harvests and fragrant with prairie roses. South Dakota is a country capable of producing from her soil everything necessary for the comfort and the blessing of the human life."

Thirteen years ago not a white man within 125 miles of where I stand; to-day a beautiful city rising, as by magic, from the lap of your lakes and from your virgin and verdant soil.

Everything about your town suggests business and social permanency; your public buildings, your mercantile houses, your pretty homes, your water-works, your electric light and gas plants, your motor lines, are what we might expect to see in a city of 50,000 inhabitants.

CODINGTON CO. COURT HOUSE, WATERTOWN.

While you have done nothing to boom WATERTOWN, but have quietly builded your homes, made beautiful your streets, your parks, and your drives, the wealth of your surroundings and the natural laws of trade and enterprise have done much for you.

GRANITE BLOCK, WATERTOWN.

Your country has been settled by stalwart and industrious farmers, who are rapidly making your rich Sioux valley, which for richness of soil equals Aguas Alientes of Mexico, and vies with the Nile and the Ganges, a country of incalculable wealth and of great beauty. Think of it, the infant State of America, yielding 22,000,000 bushels of wheat, 10,000,000 bushels of oats, 4,000,000 bushels of barley, 5,000,000 bushels of flaxseed, 25,000,000 bushels of corn, 3 000,000 bushels of potatoes, lesser vegetables in proportion, 10,000,000 pounds of wool, 5,000,000 head of horses, cattle, sheep and hogs.

You have a great system of railways, and to reproduce them would cost upwards of $210,000,000. You are connected directly by your railroads with Duluth on the north, Minneapolis and St. Paul on the east, Chicago southeast, Omaha south, the sheep prairies of Wyoming southwest, Bismarck, the Northern Pacific, with its tributaries, northwest, and the Black Hills, the centre of American tin, and the centre of many of the largest gold and silver mines in the country, in the west. So peculiar is your railroad competition that you can ship your products to the East and Europe as cheap as they can be shipped from Minneapolis, though you are 226 miles farther west.

When such great railroad corporations as the Chicago and Northwestern, the Rock Island, the Minneapolis, Manitoba and Northern, kings of travel and trade, pounce down upon your town, it means that you have something worth having; it means that you are to have a city which will direct the trade of the Northwest; a city of mills and factories sufficient to take care of your grain and fibre—woolen mills for your wool, linen mills for your flax, strawboard mills for the million tons of straw you annually waste; shoe factories for your hides, starch factories for your potatoes, sugar mills for your beets; it means mills to manufacture the products you grow as you grow them, instead of freighting them 2,000 miles east to be manufactured and then shipping the manufactured goods back to you.

SCENE ON A SOUTH DAKOTA STOCK FARM, NEAR WATERTOWN.

DENVER has become a great city, long since the pride of Colorado, but her mountains made her great.
OMAHA, the glory of Nebraska, but her prairies made her glorious.
WICHITA, the wonder of the South, but her railroads made her famous; but

WATERTOWN

has the RAILROADS of Wichita, the PRAIRIES of Omaha, and the MOUNTAINS of Denver, EACH and ALL contributing to her FUTURE GROWTH.

MAPS AND ILLUSTRATED PAMPHLETS, giving full statistical details, and describing the Lands for sale adapted for Residences, Business, Manufacturing or Agricultural purposes, sent **Free to any Address.** Apply at the offices of the

WATERTOWN LAND AND IMPROVEMENT CO., Equitable Building, Boston, Mass.

CONFEDERATE MONEY.

Warranted Genuine and in Good Condition.

We are extensive dealers in Confederate Money—rare relics of our late civil war; also Bullets, Cannon Balls, etc. We want agents in every city North to sell these mementoes, and we will pay agents handsomely to sell our goods. We will furnish the money to those desiring at the following retail prices: Shinplasters, 10, 25, 50 and 75 cents each, or the entire set 50 cents. Complete sets, consisting of $100, $50, $20, $10, $5, $2, $1, 50c., $1 per set. $500 bills, $2 50 each. $100 bills, 15 cents, or two for 25 cents. $50 bills, 10 cents, or two for 15 cents. $5 and $20, 5 cents each. 50c., $1 and $2, 25 cents each. Inquirers enclose stamp for reply.

THE QUEEN'S PRIZE SCHOOL OF HISTORY.

About two years ago the publishers of THE CANADIAN QUEEN added what has proven to be a very popular and successful feature to their publication in establishing their Prize History School. It has offered competitive examinations in English, Canadian and American History, giving valuable rewards to those making the most correct answers. During this time there have been added the names of over forty thousand new subscribers to their books. Rewards have been made by THE QUEEN which have cost them in cash over ten thousand dollars. THE QUEEN'S Prize School of History has received the sanction and support of the clergy, press, and, in fact, of the best people of the Dominion of Canada. The following, taken from a leading daily newspaper, expresses an opinion which is universal:

A HANDSOME PRIZE.

AN EVIDENCE OF WHAT A GENUINE MAGAZINE COMPETITION OFFERS.

"On Friday there arrived from Toronto, for Miss M. Hora, a handsome Shetland pony, harness and cart, being the first award in the Royal Quilt Competition of THE CANADIAN QUEEN magazine. It attests the genuine nature of the magazine's contests by its excellent condition and value. THE QUEEN has frequent competitions and has made innumerable awards, displaying a generosity quite surprising to those who have had experience of the limited field for Canadian journalistic enterprise. But THE QUEEN has been a success as a business venture from the start, and is growing in literary excellence steadily. It covers the field of fashion, as well as light reading; talks to the household, the young, and, indeed, all home classes. The competitions have been used to assist the introduction of the magazine, for where it is introduced it is quite certain to remain a monthly guest. The leading prizes have been made, as instance this latest to Kingston, while many smaller prizes have rewarded the moderately successful among competitors. THE CANADIAN QUEEN is truly royal in its ways."—*The (Kingston, Ont.) Daily British Whig*, June 27th, 1891.

QUESTIONS IN AMERICAN HISTORY.

1.—Give the names of the early navigators who it is claimed by historians first discovered America.

2.—From whom has America taken its name?

3.—What class and nationality first settled Virginia? New York? Massachusetts? Pennsylvania? Maryland?

4.—What action did the Continental Congress of 1774 take and what was the result of that action?

5.—What was the first battle fought in the War of the Revolution?

6.—What nation rendered the Americans great assistance in the War of the Revolution?

7.—Give the names of the committee appointed to draft the famous Declaration of Independence.

8.—What was the date of the signing of the United States Constitution?

9.—After becoming a nation and before the great Civil War, what were the principal conflicts which engaged the Americans?

10.—What was the direct cause of the Civil War? What Generals of the Northern Army have occupied executive positions under the Federal Government since the closing of the War? Who was Commander-in-Chief and who were the principal Generals of the Confederate Army during the struggle?

11.—How long did this War last and what is the computed loss of life?

12.—What can be said to day of the United States as a nation?

To the *First* gentleman sending the correct answers to the above questions in American History the publishers of THE QUEEN will present "**Majestic**" acknowledged the **Handsomest and Finest Riding Horse in Ontario.** ("Majestic" is sixteen hands high, thoroughbred, seven years old, and valued at $350.00.) To the *First* lady the publishers of THE QUEEN will present an elegant **Jacket of Genuine Alaska Seal** to be made according to the measurement supplied by the winner. To the *First* boy under sixteen years of age the publishers of THE QUEEN will present a **Little Giant Safety Bicycle** valued at $75.00. To the *First* girl under sixteen years of age the publishers of THE QUEEN will present an elegant **Music Box,** playing twenty tunes, finely finished and valued at $55.00.

To the gentleman from whom the *Last* correct answers are received before the close of this Competition, the publishers of THE QUEEN will present a **First Cabin Passage to Europe and Return** and **$200 in Gold** for expenses. This trip can be taken by the winner any time before October 1st, 1892. To the lady from whom the *Last* correct answers are received before the close of this Competiton the publishers of THE QUEEN will present a **Pony, Cart and Harness.** To the boy under sixteen years of age from whom the *Last* correct answers are received before the close of this Competition the publishers of THE QUEEN will present a **Solid Gold Watch** containing one of the best American movements, and valued at $75.00. To the girl under sixteen years of age from whom the *Last* correct answers are received before the close of this Competition the publishers of THE QUEEN will present an elegant **Solid Gold Watch,** containing one of the best American movements, and valued at $65.00.

ADDITIONAL PRIZES IN ORDER OF MERIT: Silver Tea Services, Ladies' Gold Watches, Silk Dress Patterns, French Mantel Clocks, Portiere Curtains, Toilet Cases, Manicure Sets, and many other useful and valuable articles.

The object of the publishers in offering these liberal prizes is to introduce THE QUEEN Magazine into **new** homes. Answers must be mailed *on or before* November 10th, 1891, and must be accompanied by $1.00 for one year's subscription to THE CANADIAN QUEEN. Prizes awarded to subscribers residing in the United States will be shipped to them **free of duty.** The distribution of awards is in the hands of disinterested persons, and decisions will be based on the correctness of answers. Use your own language in wording the answers. No corrections can be made after your answers are mailed. THE QUEEN is a large, forty-eight page family magazine, especially interesting to ladies and children, and visits regularly **over one hundred thousand of the best homes** in Canada and the United States. The awards in THE QUEEN'S Prize School of History are made strictly with regard to merit, without partiality to persons or locality. The decisions must be accepted as final. If you have never seen a copy of THE QUEEN send six U. S. two cent stamps and receive a late number, post paid, containing letters from those who have received rewards in previous contests.

Address THE CANADIAN QUEEN, PRIZE SCHOOL OF HISTORY, 58 BAY STREET, TORONTO, CANADA.

TABASCO PEPPER SAUCE,

OR LIQUID PEPPER.

Is simply the Pulp of the Ripe Pepper Extracted by Pressure.

The seed of this Pepper was obtained from Central America, and by careful cultivation in Louisiana for many years has been so improved in strength, flavor and aroma, as to have become a new variety of Red Pepper, superior to all others. The pulp is so handled as to retain all the flavor, strength, aroma and color of the ripe fruit, and to keep unimpaired in any climate. It excites the appetite, promotes digestion, and is pronounced by connoisseurs to be the finest condiment in the world. For medicinal purposes it recommends itself by its purity, strength and diffusible form.

Manufactured by E. McILHENNY'S SON,

NEW IBERIA, LA.

For Sale by all Wholesale Grocers.

NATRONA BI-CARBONATE OF SODA.

ABSOLUTELY PURE.)

The nature of the raw material from which NATRONA BI-CARBONATE OF SODA is made—viz., kryolith, a mineral containing *pure sodium*—insures a purity and uniformity of product which cannot be obtained from any other known material. In making BI-CARB. SODA from any other raw material, the use of sulphuric acid is a necessity, but none is used in any part of the process of making NATRONA BI-CARB.; hence its entire freedom from the slightest trace of arsenic, which is always present in ordinary soda. Its absolute purity and entire freedom from all traces of *sulphate of soda*, common salt and other impurities, render NATRONA BI-CARB. NEARLY TASTELESS, and being bolted through the finest bolting-cloth, insures the finest stage of division.

To these indisputable facts the attention of CONSUMERS of soda is specially called. They are IMPORTANT, and should influence both those who use and those who sell soda, to buy and sell NONE BUT THE BEST.

The NATRONA BI-CARB. Soda is kept in stock by almost every wholesale druggist and grocer throughout the United States, of whom it may be ordered.

Natrona Bi-Carb. Soda is unequaled by any other brand of English or American Manufacture.

R W ROBINSON & SON,

184 Greenwich St., N. Y

DO YOU KNOW THE DANGER OF USING SOAP?

We do not mean soap made from proper material; and when we tell you that about ninety-nine per cent. of Toilet Soap is made from refuse fats gathered from tenement houses, hospitals, butcher shops, and from cattle dying of disease or during transportation, you will, we believe stop and think. Putrefactive changes have taken place in most of this material, as it is mixed with lean meat, blood, bones, sinews, etc. There is at least *one* soap that is made wholly from vegetable material—OLIVE and PALM OILS—and that is

VELVET SKIN SOAP.

It will keep the skin soft and in a healthy condition, as no animal fats are used in its manufacture. Nothing in one's personal outfit is quite so satisfactory as a thoroughly reliable Toilet Soap. We are confident that a trial of this article will insure its continued use. If the dealer does not keep it, do not take any other, but require him to order it for you, which he can do readily. **Otherwise, send to us direct.**

LET CHILDREN SLEEP.

A plea in behalf of giving more sleep than is customarily allowed to the young has been set in circulation through the newspapers of Germany by a physician who erroneously enough is named Dr. Cold, despite the evidence he gives of being warm-hearted. A healthy infant, he says, sleeps most of the time during the first weeks; and in the early years, people are disposed to let children sleep as much as they will. But from six or seven, when school begins, there is a complete change. At the age of ten or eleven, the child sleeps only eight or nine hours, when he needs at least ten or eleven, and as he grows older the time of rest is shortened. Dr. Cold believes that, up to twenty, a youth needs nine hours' sleep and an adult should have eight or nine. With insufficient sleep, the nervous system, and brain especially, not resting enough, and ceasing to work normally, we find exhaustion, excitability, and intellectual disorders gradually taking the place of love of work, general well-being, and spirit of initiative.

AERIAL NAVIGATION.

The subject of aerial navigation has exercised men's minds for centuries, and we do not seem to be much nearer a solution of the problem it presents than that unfortunate experimenter was who at some remote period of antiquity doubtless furnished the basis for the story of Daedalus. But the experiment is being prosecuted at the present day, and the aid of modern science is being invoked to its elucidation. In the *Century Magazine* for September Professor Langley discusses the question in very hopeful language. "Above us," he says, "is the great aerial ocean, stretching over all lands and offering an always open way to them, yet a way that has never yet been trodden. Can it be that the power we have always lacked is at last found, and that it only remains to learn to guide it?" This question the writer proceeds to answer in virtually the following words: Compare the case to that which would present itself if the actual ocean had never been traversed because it was always covered with fields of thin ice, which gave way under the foot, which indeed permitted vessels to be launched and to float, but which compelled them to move wherever the ice drifted. Such vessels would resemble our balloons, and be of as little practical use; but now suppose we are told, "The ice which has always been your obstacle may be made your very means of transport, for you can glide over the thinnest ice provided you only glide fast enough, and experiments will prove not only how fast you most go to make the ice bear, but that it is quite within the limits of your strength to go with the requisite speed." All this might be true, and yet if no one had ever learned to skate every trial of this really excellent plan would probably end in disaster, as all past efforts to fly have done. Indeed, in our actual experience with the air, men have come to the same kind of wrong conclusion as would have been reached in supposing that the ice could not be traversed because no one had the strength to skate while the truth would be that man has plenty of strength to skate, but is not born with the skill. The simile is defective so far as it suggests that man can sustain himself by his unaided strength on calm air, which I believe to be impracticable; but it is the object of these experiments to prove that he has now the power to sustain himself with the aid of engines recently constructed, and by means I indicate, as soon as he has skill to direct them. If asked whether this method of flight will soon be put in practice, I should have to repeat that what has preceded is matter of demonstration, but that this is matter of opinion. Expressing, then, a personal opinion only, I should answer, "Yes." It is hardly possible that these secondary difficulties will not be soon conquered by the skill of our inventors and engineers, whose attention is already beginning to be drawn to the fact that there is a new field open to them, and, though I have not experimented far enough to say that the relations of power to weight here established for small machines will hold for indefinitely large ones, it is certain they do so hold, at any rate far enough to enable us to transport, at speeds which make us practically independent of the wind, weights much greater than that of a man. Progress is rapid now, especially in invention, and it is possible—it seems to me even probable—that before the century closes we shall see this universal road of the all-embracing air which recognizes none of man's boundaries, traveled in every direction, with an effect on some of the conditions of our existence which will mark this among all the wonders the century has seen.

THE SPEED OF CANNON BALLS.

During the past summer the government military authorities have been busily occupied in testing new systems of ordnance, and new kinds of powder at their experimental grounds on Sandy Hook. The manner in which the initial velocity of a projectile is determined is quite interesting. The instrument used for the purpose is called the Boulanger chronograph. It not only measures the velocity with which a ball or shell leaves the piece, but it records its own measurements. Two open frames are set up in front of the gun at a distance of 150 feet from each other. Wires are stretched back and forth across each of these frames, making a screen through which the projectile must pass. The wires in each of these screens form a complete electric circuit, which includes also an electric battery and an electro-magnet. When the gun is fired the projectile breaks the wire in the first screen, interrupts the circuit, and at the same time the armature of the magnet is released. In a very small fraction of a second the projectile has covered the distance to the second screen and interrupted its circuit, releasing another armature. The interval of time between the drop of these two armatures represents the time taken by the projectile to travel 150 feet. This period is so short that it is hardly conceivable. The chronograph, however, registers it accurately. Wires run from each of these screens to the laboratory near them, where are placed the chronographs, batteries, switchboard and other apparatus. The two electro-magnets in circuit with the screens are embodied in the chronograph. The first magnet has an armature, an iron rod about three feet long, which is suspended in a vertical position from its core. When the wires of the first screen are broken this iron rod falls. When the shot ruptures the wire of the second screen the armature of the second electro-magnet, which is placed a short distance below the first, is also released. It operates as a knife, and striking the side of the falling rod makes a slight mark. The distance through which the rod drops while the shot is passing from one screen to the other is indicated by the distance of the cut from the end of the rod. From this the corresponding interval of time is easily computed, and this forms the unit for the calculation of the projectile's velocity in feet per second. When it is necessary to obtain very accurate records several chronographs may be used for test-

READ PAGE 489.

ing the same shot. Of course, the rate of a projectile's velocity diminishes rapidly during its flight from the gun, and the calculations of the initial velocity must be confined to a short portion of its path immediately after it leaves the gun. Instantaneous photographs are obtained of the projectile as it strikes the target From these experiments in velocity the ordnance officer is able to determine the relative strength of different powders.

UNHEARD SOUNDS.

A POSSIBLE REVELATION FOR THE PHONOGRAPH TO ACHIEVE.

In reproducing in a recent issue of the AMERICAN ANALYST from the *Electrical Review* some suggestions of the brilliant correspondent who signs himself "The Prophet," relative to the future possibilities of the phonograph, we expressed the opinion that the writer probably had more conjectures in reserve on the same subject. Our surmise was confirmed by the appearance in last week's *Review* of the following striking article in reference to capturing sounds as yet inaudible to the human ear: There are in the human ear 3,000 little fibres which form the terminations of the auditory nerve. The existence of these fibres was made known by Corti, whose name they bear. Helmholtz showed that each one of these fibres is tuned to a particular note to which it responds. The principle upon which these fibres act is that which governs the production of sympathetic vibrations. If a cornet sounding the note C be played into the piano, it will be found that the C string of the piano will emit that note, even after the sound of the cornet has ceased. In a similar manner one of these little filaments of the ear responds to a given note, and conveys to the brain a special sensation which is always recognized as belonging to that note, and which cannot be produced by any other. It would seem to follow from this that only those notes which are represented by fibres can be perceived by the ear, and that a note having a very high or very small number of vibrations could not produce an audible effect; that the limit of audibility would vary with different ears, some having a greater and some a less number of the fibres of Corti, and that certain animals might be able to hear sounds which are too high for the human ear. It has been found that all of these things are true, and it is a matter of common observation that dogs and even savages are frequently much disturbed by noises which the civilized human ear cannot notice. It would be quite possible for beings having voices pitched at a very high key, and ears to correspond, to carry on a conversation which we would be totally unable to hear. For aught we know, the air may be at all times filled with most beautiful music. We certainly know that it is constantly agitated by sounds which we cannot hear. Shall we ever be able to listen to these unheard sounds, and the mysterious music of nature which has for centuries wasted its sweetness upon the dull ear of mankind? Science answers with the phonograph, and says that by its aid we may annex, perhaps, another world. It is conceivable that by employing a sensitive mirror vibrating a beam of light upon a moving photographic paper we may record vibrations which are too rapid for the unaided ear, and then reproduce them in the phonograph at a lower pitch, thus bringing them within our range. In the same manner vibrations which are too slow to affect our ear as music might be recorded, and then phonographically reproduced at a more rapid rate anywhere within our limits of audibility. This opens up an entirely new field of research, and may become a most important factor in the science of æsthetics. Perhaps it may demonstrate a numerical relation between harmony in music and in colors. This feature of the phonograph may become of the greatest practical importance in telephony, by making it possible to carry on a number of conversations simultaneously over one circuit. The existing systems of duplex telephony are not, strictly speaking, duplex, for there is really a circuit for each conversation. By this phonographic multiplex system it would be possible to carry on one conversation in the ordinary way, then to have a phonograph transmitting a message at such a speed that the vibrations impressed upon the line should be below the audible limit of the ear, and, consequently, having no effect on the original conversation. These slow vibrations could then be taken off upon a phonograph at the far end, and reproduced at the normal rate. In the same way one or more separate messages might be transmitted at abnormally high rates and reproduced at the usual speed. Of course, a multitude of practical difficulties exist, but there are no theoretical reasons in the way of this accomplishment. The working speed of the telephone line in the present state of the art is the most serious obstacle to be encountered. But this factor depends principally upon electro-static capacity; and while no scientist has yet practically overcome the retardation which it introduces, the significant fact remains that no one can prove that this trouble cannot be avoided on circuits of ordinary dimensions.

GIANT SLOTHS.

SOME PREHISTORIC AMERICAN MONSTERS.

While the South American megatherium and mylodon received their names from two of Europe's most eminent anatomists, it was a distinguished politician, no other than Thomas Jefferson, twice President of the United States, who stood sponsor for the first of the ancient ground-sloths found in this country. At the time of the discovery of the gigantic half-fossil bones in a cave in Greenbriar County, West Virginia, Jefferson was President of the Philosophical Association founded at Philadelphia by his friend, Benjamin Franklin. To him, therefore, were sent a few of the bones, among which three enormous claws were so conspicuous that he at first sight regarded the animal as "appearing to be of the tiger, lion, and panther species." Later, however, he announced only "the discovery of certain bones of a quadruped of the clawed kind," suggesting for the remains a name compounded of two Greek words—*megalas*, large, and *onyx*, a claw. So suitable was this designation considered that it was afterwards adopted by Dr. Wistar in his account of the bones; and when later they were described by Dr. Harlan, he also retained the name, adding to it *Jeffersonii*, to commemorate the illustrious man to whom the happy appellation was due. Remains of the *Megalonyx Jeffersonii* have come to light but slowly, and, until recently, in too fragmentary a condition to build up a skeleton therefrom. In December, 1890, however, at least a third of the required number of bones were discovered in excellent condition in Holmes County, Ohio, in a swamp to the northeast of Millersburg. Excavation, suspended by the oncoming of winter, may yet disclose more of this great animal and some fortunate museum become the owner of its complete skeleton. Meanwhile the discovery itself is of special significance, not only in the history of the megalonyx but of the whole family to which it belongs. *Megalonyx Jeffersonii*, not hitherto found north of the Ohio excepting on the Atlantic coast, is now known to have extended its wanderings at least one hundred miles further northward in the valleys of the Ohio, and no little light is thrown on the question of the length of time that has elapsed since these huge edentates were denizens of North America. The swamp, formerly one of those glacial lakes with which the front of the ice-sheet abounded, consists of peat to the depth of from five to ten feet overlaying a bed of marl formed by the deposition of silt from the glacier water. In its uppermost layer only, this marl contains a multitude of snail shells, showing that it was not till the ice-tongue had retreated to return no more, and ice-cold water had ceased to enter the lake that the water-mollusks appeared upon the scene. With them came water-plants such as are to be found in the Ohio swamps to-day, and animals that had been driven southwards by the ice, began slowly to return. Summers of exceptional warmth would even tempt hither some strange beasts from farther south. Among them, doubtless, were the megalonyx whose remains were found near Millersburg, between a tongue of gravelly drift that projects into the swamp and a small island of the same material. As its hindquarters were farthest from land the animal seems to have been swimming from one point to the other and, in attempting to land in the weedy shallows, to have been held fast by the shell-marl on which its bones were lying. The time of its death must thus have been after the final retreat of the ice had allowed the return of the snails whose shells abound in the upper layer of the marl. It must also have been long enough ago for the water-plants to form a peaty mass of five feet thickness above the bones. For this a space of six to seven thousand years will suffice. This discovery in Ohio, therefore, makes the megalonyx and his congeners, the megatherium and mylodon, creatures of yesterday, counted by geologic time. Contemporaneous with the mastodon they were, in this western world, among the foes of primitive man and that even after civilization had begun to dawn in the far west, on the rich plains of the Nile. The western world was the home of the gigantic extinct edentates, as it is now that of their modern representatives; but although half fossil remains of the former are found from time to time in North America, the southern continent must be considered to have been their favorite habitat. This fact was fully demonstrated by Charles Darwin, when, as a youth, he visited Patagonia and Buenos Ayres as naturalist to the expedition of the Beagle. Excited by the accidental discovery of some fossil bones of a gigantic edentate, he prosecuted a most diligent and intelligent search for more. Often did he spend whole nights in the work of resurrection, but more often he was compelled to return to the ship after only a few hours' labor, breaking off in despair the projecting extremity of some huge, partly excavated bone. The occurrence of these enormous bones was indicated to him in various ways—sometimes in local names, such as "The Stream of the Animal," "The Hill of the Giant." At other times a clue was given in traditions that ascribed to certain rivers the marvellous property of changing small bones into large, and to certain bones the power of growing after death. By one means and another he became impressed with the extraordinary number of the remains buried in the grand estuary deposits that form the pampas, coming to the belief that the whole area is one wide sepulchre of extinct, gigantic quadrupeds. In the north of Patagonia he actually excavated such a catacomb, finding in a space of about two hundred square yards the remains of nine extinct giants, six of which belonged to the family of edentates. The wonderful resemblance borne by these colossal edentates to the sloths and armadillos still inhabiting South America arrested the attention of the young naturalist, and turned his thoughts to questions regarding the appearance of organic beings on our earth and their disappearance from it. It was indeed the vivid impression made on his mind by excavating these fossil edentates with his own hands that formed one of the chief starting points for his speculations on the origin of species. These giant sloths have, therefore, apart from their intrinsic interest, a value that is almost sacred in every department of thought, being connected with one of the broadest generalizations that the world has ever known.—*Katharine B. Claypole in Pop. Science News.*

FINER THAN HAIR.—Platinum and silver can each be drawn into wire many times finer than human hair. The former has been drawn into wires so fine that twenty-seven of them could be twisted together into a hollow of a hair.

A DARWIN CRITIC.

WHICH REALLY SURVIVES—THE FITTEST OR THE LUCKIEST?

The struggle for existence is a fact; that it tends to the survival of slight favorable variations is an assumption. Darwin and Wallace both prove the fact, and then pursue the argument as if they had proved the assumption also. Wallace does admit that there is an element of chance in the survival. For my part, I am led to conclude that the distinction is very largely indiscriminate, and that those which survive are very often the fittest only in the sense in which the survivors in a railway accident or in an earthquake are the fittest. In a sense, we may speak of survival of the fittest as inevitable—the fittest meaning only that which has survived Used in such a sense it implies no theory at all, but used in the Darwinian sense it is misleading. I will define Darwin's position in his own words, examine some of his illustrations, and then bring forward some of my own: "(1) Natural selection acts by life and death, by the preservation of individuals with any favorable variation, and by the destruction of those with any unfavorable variation of structure. (2). Under nature, the slightest difference of structure or constitution may well turn the scale in the struggle for life, and so be preserved. (3). But the struggle will almost invariably be most severe between the individuals of the same species." Wallace defines Natural selection as "a rigid law, which acts by the life or death of individuals submitted to its action." Nevertheless, in spite of this definition, none of the illustrations brought forward by Darwin afford an instance of individuals of the same species struggling together and surviving or perishing by reason of *slight individual differences*. Many of his illustrations, in fact, tell against this argument For instance, on a piece of ground dug and cleared he marked out three hundred and fifty-seven seedlings of native weeds as they came up, and of those two hundred and ninety-five were destroyed chiefly by slugs and insects. There is not here, nor is there possible, any warranty for the suggestion that the seedlings chosen by the slugs and insects were least fitted to survive. Another example is that of certain species struggling with and overcoming others; thus, out of twenty species allowed to grow on a little plot of turf, nine species perished from the other species being allowed to grow up freely. There is nothing here to show that any of the species were modified in the process. Had some specially constituted individuals of the exterminated species survived, the experiment would have been to the point. The next example is the struggle against climate. Darwin cites the severe winter of 1854–5 as destructive of four-fifths of the birds on his own grounds. But surely this is indiscriminate slaughter. Doubtless the more vigorous do survive in such a struggle, but not in consequence of those slight individual differences which Darwinism takes as the foundation of new species. Both Wallace and Darwin, too, agree that the struggle is most severe at an early period of life. "In animals it is the eggs or very young that suffer most from their various enemies; in plants, the tender seedlings, when they first appear above ground." In other words, the greatest struggle is before the appearance of those individual differences which can be supposed to be of advantage in the struggle. It must be altogether indiscriminate as regards those slight departures from the type which are the hypothetical foundation of new species. The general Darwinian argument is that the intense struggle for existence tends to evolve individuals specially fitted to peculiar surroundings. The only evidence in favor of the theory is that there is an intense struggle, and that the survivors are best adapted to the environment. There is none that they become adapted by reason of the struggle. Wallace sets up for himself an imaginary opponent, who denies the fact of the struggle for existence, but after proving his point we find that the struggle thus pictured is not the one required, viz., one in which the slightest variation turns the scale; it is rather in which the slaughter is largely indiscriminate as respects such cases. The supposition that, when a number of individuals struggle together for existence until the majority are exterminated, the minority will grow strong and vigorous is not the only possible one, the whole race may become dwarfed and weakened, although some escape death. Strong and weak, bold and timid, species of animals exist side by side, and so, too, individuals of much varied capacity seem to have, on the average, more nearly equal chances of survival than the Darwinians realize. If, for example, the bold and strong overcome in the struggle to which the weak and timid succumb, the latter withdraw from the danger into which the former rush boldly to their own destruction. The swift will often escape while the slow are overtaken, but the "whirligig" of time brings its revenge; the slow learn cunning and caution, and escape while the swift, becoming over secure, are taken by surprise. And it seems almost a logical necessity that, if nature permits the existence of strong and weak, swift and slow, bold and timid in different and equally abundant races, equal diversity should survive and maintain the battle of life among individuals of a species. And how much more is it a question of chance than of favorable variations that determines which of the innumerable germs floating about in the atmosphere shall germinate and which not; which of the swarms of insects shall escape in the rapid flight of swallows through the air, which of the small organisms on which the whale feeds shall escape when the whale glides through shoals of them. In none of these nor in innumerable other cases which could be cited is there any ground to ascribe special fitness to the survivors. The swallow and the whale take little account of small favorable variations. If the facts of variation and the struggle for existence are to be used as the foundation of Darwinism it must be shown that the struggle is of the sort required, viz., one in which slight individual differences determine which shall survive and which perish. As I have endeavored to point out this has not been done either by Darwin or Wallace.—*London Review.*

FOOD AND SLEEP.

THE PROPER RELATIONSHIP OF REST TO DIET.

Rouxel has published in *Journal d'Hygiene*, an essay on the Art of Eating in which he says with much reason that, although rules and precepts on the best mode of eating have long been known they are little followed. Of course, in speaking of the "Art of Eating," the idea of "Art" is used in a very limited meaning. The first and best rule for sensible eating is to preserve the desire of eating (appetite) and it should not be obtained by any other means than by proper exercises, physical and mental work which should be made useful at the same time. The transformation of matter which is most active during work, causes the consumption of aliments received in the body for the purpose of replacing the physical forces consumed, as well as the secretion of all used up matters by the natural channels. Besides work, a convenient interval between the meals is necessary, to enable the stomach in the meantime, without being disturbed by new ingestions, to accomplish its task. As a second means for "good eating," the ancients employed baths, attritions and massage of the body before the principal meal. Epicurus, it is stated, recommended to be more careful in the choice of table-companions than of food, a prescription which will always be less observed than it deserves to be. Pleasant company at table has certainly a beneficial and stimulating action, although it would not remedy the defective quality of the viands. The best food is food of easy digestibility, provided they contain the necessary amount of nutritive matter. The important point is, not what is eaten, but what is digested. Mixed animal and vegetable food, the latter in preponderating quantity, is generally best accepted by the body. Rules of strictly general value cannot be given and the author might have quoted the famous "de gustibus non est disputandum." With much reason the author points out as a fifth rule observance of the right measure in eating (and drinking.) He who indulges in excesses either in eating or in drinking, says Brillat-Savarin, does not understand how man should eat and should drink. Eating before the preceding meal is digested, is injurious beyond a doubt. For the purpose of facilitating digestion it was thought conducive in former times, to take exercise after eating; we know now-a-days that a short physical and mental rest is the best means of inviting digestion.

ROCK BAROMTER.—Mexico has a rock that serves as a weather prophet, by changing color with every approaching change in the weather.

SPEEDY DEATH.—A velocity as high as 2,887 feet per second has been attained by a projectile from a rapid-fire gun. This is at the rate of 1,968 miles an hour. It is the highest velocity yet recorded.

INCREASED VALUE.—At Waltham a single pound of steel costing 50 cents is manufactured into 100,000 screws, which are worth $11. They look about like iron filings, and it needs a microscope to distinguish them as screws.

A WASP MYSTERY.—It is known that wasps' nests often take fire, supposed to be caused by the chemical action of the wax upon the paper material of the nest itself. May this not account for many mysterious fires in barns and out-buildings.

COMPOSITION GRINDSTONES.—Artificial grindstones, made of a mixture of pulverized quartz, powered flint, powdered emery or corundum, and rubber dissolved by a suitable solvent, are now made for sharpening tools which outwear by years any natural stone known.

SINKING MOUNTAINS.—Four different mountain peaks in Idaho are from 13 to 23 feet lower, by actual measurement, than they were fifteen years ago, and it is believed that this settling is going on with many others. The idea is that quicksands have undermined them.

HEAVENLY WONDERS.—The great Lick telescope reveals about 100,000,000 stars, and every one of them is a sun, theoretically and by analogy giving light and heat to its planets; this telescope reveals stars so small that it would require 30,000 of them to be visible to the naked eye.

IMPROVED GLASS.—A new Swedish glass is claimed to have important advantages for microscope and other fine lenses, giving greatly increased power. The chief improvement over other fine glass consists in the addition of phosphate and chlorine, which impart absolute transparency, great hardness, and susceptibility of the finest polish.

AIR BOAT.—The Aerial machine which Mr. H. Maxim is having constructed at Crayford is nearly completed. It will be propelled through the air by a light screw making 2,500 revolutions per minute, and, according to the inventor, will be capable of transporing through the air about 30,000 pounds of freightage. —*The European Mail*, London.

DIAMOND INK.—So called diamond ink for writing on glass, is a compound of fluoric acid and barium; the latter has no effect, it being simply a white powder to give body to the acid. The ink can be used with a rubber hand stamp, and it should be allowed to remain fifteen minutes, when the barium will brush off, leaving the design on the glass.

ROMAN DISH.—The Romans were epicures and one of their favorite dishes was made of the large white snails which abound in the Italian woods. So fond of this dish were they that when their legions were stationed in Britain after the conquest it was considered necessary to import these snails. Their progeny exists in large numbers in several places in England at the present day, notably at Birdlip, near Cheltenham.

BRIGHT STORIES.

A MYSTERIOUS GUEST.

From the French of Honore de Balzac.

"Sometimes they saw that by some phenomenon of Vision or Locomotion he could abolish Space in both its moods—Time and Distance—whereof the one is intellectual and the other physical."—LOUIS LAMBERT.

One evening in the month of November, 1793, the principal inhabitants of Carentan were collected in the salon of Madame de Dey, who held an assembly every evening. Certain circumstances which would have attracted no notice in a large town, but were such as to mightily interest a small one, imparted a peculiar importance to this customary gathering. Two days before Madame de Dey had closed her doors to her visitors on the ground of indisposition, and had also announced that she would be unable to receive them the following evening. At an ordinary time these two events would have produced the same effect at Carentan as a *relache* at all the theatres produce in Paris; on these days existence seems in a sense incomplete. But in 1793 the action of Madame de Dey was one which might lead to the most disastrous consequences. At that time a step involving a noble in the least risk was nearly always a matter of life and death. In order to understand thoroughly the keen curiosity and petty craftiness which on that evening animated the faces of all these respectable Normans; and still more, in order to share the secret perplexities of Madame de Dey, it is necessary to explain the part she played at Carentan. As the critical position in which she was situated at this time was, no doubt, the position of many during the Revolution, the sympathies of not a few of my readers will add their own color to this narrative.

Madame de Dey was the widow of a lieutenant-general decorated with several orders. At the beginning of the emigration she had left the court, and as she owned considerable property in the neighborhood of Carentan, she had taken refuge there, in the hope that the influence of the Terror would make itself but little felt in those parts. This supposition, founded on an exact knowledge of the country, proved correct, for the ravages of the Revolution in Lower Normandy were slight. Although formerly, when she came to visit her property, she had only associated with the local *noblesse*, now, out of policy, she opened her doors to the principal townspeople and the new authorities of Carentan, exerting herself to flatter them by the compliment of her acquaintance, and at the same time to avoid awakening their hatred or their jealousy. Kind and courteous, gifted with an indescribable sweetness of manner, she knew how to please without recourse to cringing or entreaty, and had thus succeeded in winning general esteem. This was due to her exquisite tact, which by its sage promptings enabled her to steer a difficult course and satisfy the exigencies of a mixed society; she neither humiliated the tetchy self-conceit of the parvenus nor shocked the sensibilities of her old friends.

At the age of about thirty-eight she still preserved, not that fresh, buxom beauty which distinguishes the girls of Lower Normandy, but a slender, so to speak, aristocratic type. Her features were delicately chiseled and her figure pliant and graceful; when she spoke her pale face seemed to light up with fresh life. Her large dark eyes were full of kindly courtesy, but an expression of religious calm within them seemed to show that the principle of her existence lay no longer in herself. She had been married at an early age to an old and jealous soldier, and the falseness of her position in the mist of a dissolute court had, no doubt, done much to spread a veil of grave melancholy over a face which must once have beamed with all the charm and vivacity of love. Obliged to repress unceasingly the instinctive impulses and emotions of woman at a time when she still feels rather than reflects, with her passion had remained virgin in the depth of her heart. Thus her chief attraction was derived from this inward youthfulness, which betrayed itself at certain moments in her countenance, and gave her ideas an innocent expression of desire. Her appearance commanded respect, but in her manner and her voice impulses towards an unknown future such as spring in the heart of a young girl were continually showing themselves. The least susceptible men soon found themselves in love with her, and yet were impressed with a sort of fear of her, inspired by her courtly bearing. Her soul, great by nature but rendered strong by cruel struggles, seemed to be raised too high for common humanity, and of this men appeared to be conscious. To such a soul a lofty passion is a necessity. Thus all Madame de Dey's affections were concentrated in one single sentiment—the sentiment of maternity. The happiness and pleasures of which she had been deprived as a wife she found again in the intense love she bore her son. She loved him, not only with the pure and deep devotion of a mother, but with the coquetry of a mistress and the jealousy of a wife. She was miserable when he was far from her, anxious when he had gone out; she could never see enough of him; she lived only in him and for him. To give an idea of the strength of this sentiment in Madame de Dey, it will be enough to add that this son, besides being her only child, was the last relation left her, the only creature on whom she could fasten the hopes and fears and joys of her life. The late count was the last of his family, and the countess the sole heiress of hers, so that every worldly calculation and interest combined with the noblest needs of the soul to intensely in her heart a sentiment already so strong in the heart of woman. It was only by infinite care that she had succeeded in rearing her son, and this had endeared him still more to her. The doctor had pronounced twenty times over that she must lose him, but she was confident in her own hopes and presentments. So in spite of the decrees of the faculty she had the inexpressible joy of seeing him pass safely through the perils of infancy, and then of watching with wonder the continued improvement of his health.

Thanks to her constant care, her son had grown into a young man of so much promise that at the age of twenty he was looked upon as one of the most accomplished gentlemen at the Court of Versailles. Above all, happy in a crown unattained by the efforts of every mother, she was adored by her son; they understood one another heart to heart in fraternal sympathy. If they had not been already bound together by the bonds of nature, they would have instinctively felt for each other that mutual friendship between men which is so rarely met with in life.

The young count had been appointed sub-lieutenant at the age of 18, and in obedience to the code of honor of the day had followed the princes in their emigration.

Thus it was impossible for Madame de Dey, being noble, rich, and the mother of an emigrant, to hide from herself the dangers of her cruel situation. With no other aim than to save her large fortune for her son, she had given up the happiness of accompanying him; but when she read at Carentan the stringent laws under which the republic was confiscating every day the property of emigrants, she exulted in her act of courage, for was she not preserving her son's wealth at the risk of her own life? Later on, when she heard of the terrible executions decreed by the convention, she slept in peace, knowing that her only treasure was in safety, far from danger and the scaffold. She congratulated herself in the belief that she had taken the best means of preserving both her treasures at once. By consecrating to this secret thought the concessions which those unhappy times demanded, she neither compromised her womanly dignity nor her aristocratic convictions, but hid her sorrows under a cold veil of mystery.

She had grasped all the difficulties which awaited her at Carentan. To come there and fill the first place was in itself a daily tempting of the scaffold. But supported by her motherly courage she was enabled to win the affection of the poor by consoling the misery of all without distinction, and to make herself indispensable to the rich by ministering to their pleasures.

She entertained at her house the *Procureur* of the Commune, the Mayor, the President of the distict, the Public Prosecutor, and even the judges of the Revolutionary Court. Of these personages the first four were unmarried, and paid their addresses to her. Each of them hoped she would marry him, either from fear of the harm that it was in their power to do her, or for the sake of the protection which they had to offer her. The Public Prosecutor, formerly an attorney at Caen, employed to manage the Countess' business, adopted an artifice which was most dangerous for her. He tried a generous and devoted line of conduct, in the hope of inspiring her with affection. In this way he was the most formidable of all her suitors, and as she had formerly been a client of his, he alone knew intimately the condition and extent of her fortune. His passion was therefore reinforced by all the desires of avarice, and further supported by immense power—the power of life and death over the whole district. This man, who was still young, proceeded with so fine a show of generosity that Madame de Dey had not as yet been able to form a true estimate of him. But despite the danger of a trial of craft with Normans, she made use of all the inventive wit and duplicity bestowed by nature on women, to play off these rivals one against the other. By gaining time, she hoped to reach the end of her difficulties, safe and sound. At this period the royalists of the interior went on flattering themselves from day to day that on the morrow they would see the end of the Republic; it was this persuasion which brought many of them to ruin.

In spite of these difficulties, by the exercise of considerable address, the Countess had maintained her independence up to the day on which she had determined, with unaccountable imprudence, to close her doors to her guests. She inspired such a real and deep interest, that the people who had come to her house that evening were seriously perturbed when they heard it was impossible for her to receive them. Then, with that barefaced curiosity which is ingrained in provincial manners, they immediately began to make inquiries as to what trouble, or annoyance, or illness, she suffered from. To these questions an old housekeeper, named Brigitte, answered that her mistress kept her room and would see no one, not even the members of her household.

The semi-claustral life led by the inhabitants of a small town forms a habit of analysing and explaining the actions of others, so germane to them as to become invincible. So after having pitied Madame de Dey, without really knowing whether she was happy or unhappy, each one set himself to discover the cause of her sudden retirement.

"If she were ill," said the first inquisitor, "she would have sent for advice; but the doctor has been at my house the whole day playing chess. He was joking with me and saying that there is only one disease nowadays . . . and that's incurable."

This jest was hazarded with caution.

Men and women, old and young, set themselves to scour the vast field of conjecture; each one thought he spied a secret, and this secret occupied all their imaginations.

By the next day their suspicions had grown more venomous. As life in a small town is balanced up to date, the women learned, the first thing in the morning, that Brigitte had made larger purchases at the market than usual. This was an indisputable fact. Brigitte had been seen very early in the *Place*, and—marvellous to relate!—she had bought the only hare there was to be got. Now the whole town knew that Madame de Dey did not care for game, so this hare

became the object of endless speculation. Then as the old men were taking their usual stroll they observed a sort of concentrated activity in the Countess's house, betrayed by the very precautions that the servants took to conceal it. The valet was beating a carpet in the garden ; the evening before no one would have noticed it, but as every one was constructing a romance of his own, this carpet served them for a foundation. Each person had a different tale.

The second day, the principal personages of Carentan, hearing that Madame de Dey announced that she was unwell, met for the evening at the house of the Mayor's brother, a retired merchant. He was a married man, honorable, and generally respected, the Countess herself having a great regard for him. On this occasion all the aspirants to the rich widow's hand had a more or less probable story to tell, while each of them pondered how to turn to his own profit the secret which obliged her to compromise herself in the way she had. The Public Prosecutor imagined all the details of a drama in which her son was to be brought to the Countess by night. The Mayor believed that a priest who had refused the oaths had come from La Vendée, and sought refuge. The President of the district was convinced it was a Chouan or Vendéan leader, hotly pursued. Others inclined to a noble escaped from the prison in Paris. In short, everybody suspected that the Countess had been guilty of one of those acts of generosity, denominated by the laws of that time "crimes," and such as might bring her to the scaffold. However, the Public Prosecutor whispered that they must be silent, and try to save the unfortunate lady from the abyss into which she was hurrying.

"If you publish this affair abroad," he added, "I shall be obliged to interfere, search her house, and then——!" He said no more, but every one understood his reticence.

The Countess's true friends were so much alarmed for her, that, on the morning of the third day, the *Procureur Syndic* of the Commune got his wife to write her a note, entreating her to hold her reception that evening as usual. The old merchant, bolder still, presented himself during the morning at Madame de Dey's house. Confident in his desire to serve her, he insisted on being shown in, when to his utter amazement he caught sight of her in the garden, engaged in cutting the last flowers in her borders to fill her vases.

"There's no doubt she has given refuge to her lover," said the old man, struck with pity for this charming woman. The strange expression of her face confirmed his suspicions. Deeply moved by a devotion natural in woman but always touching to us,—because every man is flattered by the sacrifices a woman makes for one of them,—the merchant informed the Countess of the reports which were going about the town, and of the danger she was in.—"For," he concluded, "if certain of our functionaries would not be disinclined to pardon your heroism, if a priest were the object, no one will have any pity on you, if it is discovered that you are sacrificing yourself to the dictates of the heart."

At these words Madame de Dey looked at him in such a strange, wild way, that, old man as he was, he could not help shuddering.

"Come," said she, taking him be the hand and leading him into her own room. After making sure that they were alone, she drew from her bosom a soiled and crumpled letter. "Read it," she cried, pronouncing the words with a violent effort.

She fell back into her easy-chair completely overcome. Whilst the old merchant was looking for his spectacles and wiping them clean, she raised her eyes to his face, and for the first time gazed at him curiously ; then she said sweetly, and in a changed voice ; "I can trust you."

"Am I not going to take a share in your crime?" answered the worthy man simply.

She shuddered. For the first time in that little town her soul found sympathy in the soul of another. The old merchant understood immediately both the dejection and the joy of the Countess. Her son had taken part in the expedition of Granville, he had written to his mother from the depth of his prison to give her one sad, sweet hope. Confident in his plan of escape, he named three days within which he would present himself at her house in disguise. The fatal letter contained heartrending *adieux* in case he should not be at Carentan by the evening of the third day. He also entreated his mother to remit a considerable sum of money to the messenger who had undertaken to carry this missive to her, through innumerable dangers.

The paper quivered in the old man's hands.

"And this is the third day," cried Madame de Dey. Then she rose hastily, took the letter, and began to walk up and down the room.

"You have not been altogether prudent," said the merchant. "Why did you have provisions got in?"

"But he may arrive dying with hunger, worn out with fatigue, and——" she could not go on.

"I am certain of my brother," answered the old man ; "I will go and get him on your side."

(*Concluded next week.*)

DOMESTIC DIETETICS.

SPECIALLY PREPARED, FROM PRACTICAL TESTS, FOR THE LADY READERS OF THE "AMERICAN ANALYST."

SEASONABLE FOOD.

October.

MEATS.—Beef, mutton, ham, kidneys, liver, venison, sausage.

GAME AND POULTRY.—Pigeon, chicken, duck, woodcock, brant, grouse, partridge, rabbit, snipe, goose.

FISH.—Bass, blackfish, bluefish, clams, cod, crabs, eels, carp, catfish, flounder, halibut, herrings, lobster, mackerel, mussels, oysters, pike, porgie, prawn, rockfish, salmon, sea bass, sturgeon, smelt, turtle, white fish, whiting.

VEGETABLES.—Artichokes, beets, beans, broccoli, Brussels sprouts, cabbage, carrots, cauliflower, corn, cucumbers, egg-plant, garlic, lettuce, onions, parsley, parsnips, potatoes, radishes, rhubarb, savoy, shallots, spinach, squash, tomatoes, turnips, watercress.

FRUITS.—Apples, bananas, blackberries, grapes, melons, oranges, peaches, pears, pineapples.

PRACTICAL RECIPES.

FRENCH SOUP.—Put two or three pounds of lean beef to boil with some thyme, parsley, a little salt, and sufficient water to cover it. When the meat has boiled until it is ready to fall to pieces remove it from the pot, skim the grease from the remaining soup and add a few young carrots and small white onions sliced, also a few cloves and allspice. Just before serving add two teaspoonfuls of brown sugar. Do not thicken.

SAUCE PIQUANTE.—Put one-half cup of vinegar to boil with a little pepper and thyme ; let it boil until it is reduced to one-half, then add three-quarter cup of broth or clear gravy and let it boil again until it is reduced one half, add a little salt and serve.

APPLE SAUCE FOR ROAST GOOSE.—Take fine tart apples, pare, core and slice them, put them in a stew pan with a very little water and cook gently until soft and tender, mash them to a paste with butter, nutmeg and sugar, to make them very sweet. Be careful that the sauce is not thin and watery.

ROAST WILD DUCK.—Have a very hot fire. Put your ducks in the oven and cook only fifteen or twenty minutes, basting almost constantly. Have ready the juice of a lemon, a little hot butter, a little cayenne pepper, a dust of sugar and a wine glass of port, all mixed together. When you lay your ducks on the hot platter, score them with a sharp knife, four times down the breast, pour the dressing over them, garnish with parsley and serve.

MRS. M's FIG CAKE.—Make a batter of one cup of sugar, one-half cup of butter, one and a half cups of flour, two eggs, one teaspoonful baking powder, a little salt, and vanilla or lemon flavoring. Bake in three layers and put between them the following mixture :

Filling.—One cup of sugar, one-quarter cup of water, boil to a syrup, or until it will "thread;" chop eight figs very fine, take sugar from stove, cool five minutes, add beaten white of one egg, beat five minutes, then add figs

SPANISH CREAM.—Put one box gelatine in a saucepan on the fire and dissolve it in a little hot water. Let three pints of milk come to the boil, stir in the gelatine, then add the well-beaten yolks of six eggs with nine spoonfuls of sugar mixed into them ; stir up and take from the fire and add the whites beaten to a stiff froth. Flavor with a little vanilla and half a tumbler of wine, and mold.

SOUR CREAM CAKE.—Make a cup cake and bake it in layers. Beat up the yolks of two eggs with three tablespoonfuls of sugar, stir in a cup of very thick sour cream, add one-half pound almonds blanched and chopped, and put this mixture between the layers of the cake.

TABLE CONTRASTS.

ENGLISH GASTRONOMY FROM A FRENCH POINT OF VIEW.

In the October issue of the *Woman's World*, Emilie Lebour-Fawsett discusses the English and French customs and eccentricities of their respective gastronomical pleasures. We are told the English cannot be excelled anywhere in the refined ways in which most of their dishes are served, and their tables laid, whenever they have company. What can be nicer than the pretty fringed doileys placed under the pie-dishes to steady them, the pretty multi-colored cut-out papers encircling the pies or fruit tarts so as to hide the generally burnt edges of the dishes? Yes, there is no doubt about it, the English have more refined refinements than the French, and there is no end to the tempting novelties constantly appearing in the shops. Ever since I have been in England I have made it my duty not only to adopt these nice inventions, most of them conducing to comfort, but to endeavor to introduce them into my native land, where I am sorry to say they have not always received the welcome which in my humble opinion was their due. I remember having seen years ago a play in France, where tea being introduced and the sugar basin being handed to the hero, he took hold of the tongs in a puzzled manner, and after pretending for some time to ignore them at last uttered a joyful exclamation, and attracted the attention of the whole company by saying, "This is the way! this is the way!" at the same time delicately taking a piece of sugar between his finger and thumb and placing it with great difficulty in the tongs, after which he dropped the sugar triumphantly into his teacup, eloquently eulogizing the usefulness of the invention. Another very useful article not altogether, but pretty generally ignored abroad, is the salt-spoon. A salt-spoon is actually in the present day an article of luxury there, and you may esteem yourself very lucky when you meet with a little ivory spade-like one in the salt cellar. Fish knives, again, are another implement perfectly unknown or unappreciated in France, and whenever I have presented friends there with a box of them, they have been regarded as being too pretty for general use, and have been carefully wrapped up and put away for grand occasions ; and as on grand occasions the guests are very numerous, they were then not in sufficient number to be useful, and were finally esti-

mated as being only a pretty, useless toy. Another thing which is an equal object of astonishment to both French and English people is the different sizes of the plates used in the two countries. "What small plates!" exclaim the latter; they are like cheese plates." "*Quelles grandes assiettes!*" cry the former; "*ce sont de vrais plats!*"—and indeed they are larger And so are the glasses, and the knives and forks, and the soup tureens, and the dishes—oh, the dishes!—and the formidable, handsome dish covers, what a show they make on the table! But how I lament their being taken away as soon as they have acted their part, namely, to make a grand show! Consequently, whilst one is eating a first help of whatever they were intended to keep hot, their viands are inevitably getting cold, and the gravy is becoming set all round; and, however tempted you might otherwise be to accept a second help, you are compelled to decline it, not being of the tribe of those amiable husbands who will not make themselves disagreeable over a lukewarm dish of hashed mutton. The real use of dish covers is so absurdly ignored in this their mother country that I actually know people who will not allow their best covers to be warmed before being placed over the dishes for fear of their being spoilt, so that their object is completely defeated, for a cold cover put on only for a few minutes is more likely to chill the joint and the gravy than to keep them hot. A relative of mine, an officer in the French army, could not speak enough of the nice large houses he had visited in London, of their comforts and luxuries, of the space allotted to every one, from the fact of each family occupying a whole house, and the trees in the park, of the splendid horses and delightful fours-in-hand, and most particularly of the beauty of the British women. Where he was most amusing was in his description of a dinner party he had been present at in London. As every good epicure ought to do, he began by studying his menu, and had made his choice of the fish, and the different entrees which he preferred, but, through some incomprehensible mishap, he was offered the dish he did not want after seeing the last portion of his elect taken by his next neighbor. This was due to the extraordinary custom, unheard of abroad, of having a short supply of each entree, and two different ones going the round of the table at the same time. While he was talking a piece of saddle of mutton was placed before him without any adjunct or gravy whatever, and he was beginning to attack it, when a butler came with a tray containing some gravy and some currant jelly. The gravy seemed to him an absolute necessity, but the currant jelly! What had currant jelly to do with roast mutton? He looked at his wife, who was placed rather far from him, and saw her complacently consuming the currant jelly with her mutton in the most natural manner imaginable. He threw a stealthy glance at his neighbor, a lovely girl, and she, too, seemed to revel in the jelly, so he desperately followed suit. Was the jelly to be used instead of salt? No, for the salt-cellar was handed most gracefully to him, and he was wondering what this unnatural amalgamation was going to produce, when a dish of potatoes appeared at his elbow, and another of cauliflower. He looked at his plate, he placed some cauliflower in a nice retired corner of it, and was about to cut his first mouthful, when another vegetable dish is at his elbow. This time he cannot hesitate, for it is his favorite vegetable, asparagus, which he had specially marked in his menu, and the dinner taking place as it did in March, made this, always a delicacy, a still greater treat so early in the season. What is he going to do? A rapid look thrown over his plate cannot discover an empty place. He thinks of telling the footman to bring them round again in a few minutes, but in a few minutes they will all be gone, like the chosen entrees, and he will have to go without any. No, he has made up his mind, and the asparagus tumbles, one after the other, into the plate, over the meat, the potatoes, the cauliflower, the jelly, in the gravy—it is a regular *pele-mele*, completed by the necessary addition of the thick creamy melted butter brought by another servant. Why have not the plates little wells on their edges? However, he must have it; how could he eat his asparagus without melted butter? and he deposits a spoonful of this excellent looking compound anywhere in his plate. Now he begins to breathe. A side glance thrown to his right, then to his left, shows him plates in beautiful order, and the ladies seem to dispose very comfortably of all the viands which in his unfortunate plate are elbowing each other in the most helter-skelter way imaginable. He can no longer find the meat, though he probes for it with his fork. At length, between two stalks, he perceives his meat, he makes a dart at it with his fork, but the whole heap seems to undergo a sort of *bouleversement*. To establish the equilibrium he will take one of the asparagus, but to his dismay he sees all the company cutting the tips off and eating them with their forks. Shall he do the same? No, never! he gives up the idea of his meat, now surrounded with the coagulated butter, and takes delicately between his finger and thumb the long-coveted comestible, and after dipping it thoroughly in what he conceives to be the melted butter, finds too late, when it reaches his mouth, that it is strongly impregnated with currant jelly! Horror! he puts it down, looks for his finger-glass to dip his fingers in—English custom allows these only at dessert—and so he smears his napkin without, however, being able to rid himself of his sticky discomfort.

NATURE'S REMEDY.

THE BENEFIT OF FRUIT AS A HEALTH PRODUCER.

Of the many sweet-scented and palatable fruits which greet the eye in garden and forest, only some berries, the wood apple, and the medlar grew wild in Germanian forests. The better varieties of fruit came later from Italy and the Rhineland, but even in Italy most of the fruits had originally been introduced from the East and rendered native by culture. The especial art of ennobling fruit by raising from seedlings, crossing, etc., originated in Belgium. Naturally enough, the medical profession, which rightly or wrongly ascribed therapeutic properties to every product of the animal, vegetable and mineral kingdom, were not slow to ascribe special virtues to every fruit of the garden from the wild blueberry to the red-cheeked Vorsdorfer apple. Fruit was especially recommended for stilling the thirst in fever and also for costiveness, and to vary the diet. In the year 1778 we find Stolpertus, a physician of the Palatinate, writing as follows: "How much it is to be wished that the apothecaries would eliminate their *edelsteinpulper*, etc., from their official list, and substitute for them neat, white wicker baskets with fruit in season, turning in this way the half of the apothecary shop into a fruit store." Special fruit treatment was unheard of until a few decades ago, when the grape cure first came into repute. The treatment originated with the patrician families of Bern (Switzerland), who, in the autumn, used to visit the Vaud, in which they owned the principal estates, and indulge freely in the fruit of the vineyard. Of late years the value of fruit as a wholesome article of diet is becoming more generally appreciated, but by no means as extensively as it deserves. At the same time fruits vary to some extent in their properties, and before they can be utilized to best advantage the special qualities and action of each require to be well known. In the matter of nutrition, fruit contains little more than sugar and organic salts, the acidity giving them their characteristic taste and special aroma. The gelatinizing substance of fruit jellies is pectine. Albumen and proteids, and the substances which enter into the structure of the animal organism, are insignificant in quantity. There is as much albumen in an egg as in a pound of cherries, 18 ounces of plums, 2½ pounds of apples, or 4 pounds of pears. Fruit, consequently, contributes very little to the support of the system, but a great deal towards its maintenance in health. Its flavor, and not its nutritious contents, is the prime element of value; and this flavor varies with the proportion of sugar, acid, gum and pectine. The last substance holds the acid concealed, so that it is scarcely appreciable to the nerves of taste. The flavor of fruit depends further on the relation between its soluble and insoluble substances. To this is due the pleasant sensation which we experience in the mouth when we eat fruit. The peach and the plum dissolve on the tongue, because they are comparatively deficient in insoluble pectose and cellulose, while the whortleberry, for example, being rich in these insoluble substances, behaves differently. The sugar-content of fruit increases with cultivation, and the proportion of free acid and insoluble substances decreases, as may be noticed markedly by a comparison between the wild and cultivated strawberry. In abundant fruit years, too, fruit is sweeter and more juicy than in seasons of poor crops. An important discovery made by Dr. C. Bender, is that fruit gives off a great deal of carbonic acid, both in the garden and in the process of hoarding in the house; it is hence very prejudicial to the lungs, to sleep in a room in which apples, pears, etc., are being stored. As regards the physiological action of fruit upon the system, it may be said, in general terms, that the acid fruits, as currants, plums, etc., act as laxatives, while the sweet fruits, as strawberries, pears, and sweet bursting grapes, have an opposite tendency. Some people are, however, very sensitive to fruit acids, and cannot indulge without being troubled with numerous little sores on the inside of the lips. In such cases it is, of course, better to forego the indulgence. The core, peeling and other cellular substance of fruits is indigestible, and should not be swallowed, the more especially that, being undigested in the stomach, they may create a stoppage in the intestinal canal. Children should be especially cautioned on this head. Unfortunately, many physicians are not sufficiently well-informed as to the direct beneficial operation of fruit in certain diseases. Professor Uffelman has repeatedly drawn attention to the beneficial effect of fruit in chronic indigestion, and catarrh of the stomach, especially after excessive indulgence in spirituous drinks, also hæmorrhoids, tendency of blood to the head, scorbutic complains, and in certain diseases of the liver and milt. In every form of febrile complaint fruit juice, or the cold juice of boiled fruit, is extremely refreshing. It has been remarked that calculus is very rare in cider districts, potash is secreted in the organism of the cider drinker and acts on lime secretions like Vichy water. The regular fruit treatment is confined mainly to the grape cure. This fruit is longest in season, and produced in greatest abundance As regards the quantity consumed daily in chronic diseases, the patient ordinarily begins with a quantity which is gradually increased to six pounds a day. The grapes are not eaten fresh from the vine, for fear of chilling the stomach, especially in the early morning. Preference is given to fruit which has been gathered two days. An interval of from an hour and a half to two hours is allowed to elapse between the meal of grapes and of other food. Milk before or after fruit is not admissible. Fruit in season should be on the table of every household from morning to night, that young and old may help themselves, to their benefit and delight.—*Ueber Land und Meer.*

AVERAGE AGE.—There are about 105 women to every 100 men; one-quarter of the population of the world die before the age of 17 years; only one in 1,000 lives to be 100 years old, and only six in 1,000 reach 75.

COMPOSITION OF WATER.—Oxygen is a gas whose presence is necessary before the phenomenon of burning can take place, and hydrogen is a gas that burns with a pale blue flame, and yet the combination of these two gases forms water, which is the opposing element of fire.

OUR HEALTH IN AUTUMN.

Perfect health demands conformity on the part of the individuals to the conditions and changes in his surrounding circumstance. Any one who eats, drinks, and dresses the same the year through in a temperate climate is bound to pay the penalty of his carelessness in the form of sickness and pain. Besides this principle which, though self-evident, is too often overlooked and neglected is another of great importance. It is that every one in passing from one season to another should aid his system to meet the exigencies of the change that has occurred and also that of the one which is soon to happen. The first point to be observed is respecting the diet. The common practice of dropping the light vegetables and fruits of summer and replacing them with the heating meats and heavy dishes of winter is altogether objectionable. The system is not yet prepared for the latter kind of food, and will not be until the cold weather has set in for good. It is much better to continue the light diet of the dog-days as long as possible. Nature gives a wise hint in supplying the heavy apples and pears, the fall potatoes and later on the rich and wholesome nuts of the forest. These supply all the necessary heat as well as the material required in the upbuilding of maintenance of the body. The next point is as to exercise, fresh air and sunlight. Now, is the time for long walks, rides, and drives, for out-of-door sports, and for everything which tends to impart tone and strength to the muscles and sinews. The heat of July and August tend to produce lassitude, indolence and physical feebleness. September, October and November are the breathing-spell in which men and women can put themselves into a condition which will bid defiance to all the ills and discomforts of winter Many people labor under the impression that the autumn-air, especially after nightfall is injurious to health. The notion is absolutely devoid of truth. On the contrary the atmosphere is singularly free from malaria and disease germs. Every room should be thoroughly ventilated and every sleeping-room should have a window or other aperture open to insure free circulation of the air. In the third place, great care should be used as regards clothing. The pores are all open from the summer heat and the system is liable to colds from sudden changes in the temperature. The mere changing of apparel is not sufficient. What is needed is not so much the replacing of the light flannels and serges of the dog-days by the heavy and closely worn fabrics so common in American life, as the protection of the body by warm and yet loosely-woven underwear. The moment cold weather sets in the gauze undergarments of summer should be replaced by woolen ones. With woolen stockings and undersuits, a person can wear summer clothing into the Christmas holidays without danger of colds or rheumatism. On the other hand, heavy clothing and overcoats without woolen undersuits will not protect, but will generally produce the ills to prevent which they are worn. Last of all and most important, the tissues of the system should be cleaned and purified by Ayer's Sarsaparilla. The heat and moisture of midsummer have so wrought upon the system as to impair its tone and leave humors in its various parts. The effect is usually seen in a feeling of fatigue, in yellowish or blood-shot eyes, in a furred tongue, in constipation or its opposite dysenteric troubles, in loss of appetite, indigestion or liver-ailments. These in themselves are not diseases, neither do they require medicine. They are the symptoms and fore-runners of possible disease and require a mild tonic and alterative to tone up and strengthen the vital functions and to dispel all foreign or worn-out matter from the organization. A simple course of Ayer's Sarsaparilla accomplishes all this and much more. It does not interfere with the appetite or digestion, neither does it injure the bowels as do so many so-called blood-purifiers. It restores the normal activity of the liver, kidneys and lymphatics, and in this way removes all unhealthful bodies from the blood, the skin and the deeper tissues. Within a fortnight the complexion is clear and attractive, the eyes bright, the tongue clean and a feeling of high spirits and superb health pervades the system. By following these hints, a person will pass the autumn in perfect physical welfare and will be prepared to meet the strains and ills of the winter season, no matter how severe they may be.

BUSINESS NOTES.

CANNED DELICACIES.

Several new departures have been made by Messrs. Armour & Co., of Chicago, in their canned meats. Each can of preserved meat is now supplied with a patent key attachment for opening it. Another feature is the packing of condensed mince meats in 12-oz. boxes, and the packing of selected pickled meats—among them boneless pigs' feet, honeycomb tripe, lambs' tongues and sliced calves' feet, properly spiced and cooked, into fancy glass jars of various sizes, to be used as luncheon delicacies.

HORSFORD'S ACID PHOSPHATE,

for indigestion, dyspepsia, and diseases incident thereto. Dr. O. C. Stout, Syracuse, N. Y., says: "I gave it to one patient who was unable to transact the most ordinary business, because his brain was 'tired and confused' upon the least mental exertion. Immediate benefit, and ultimate recovery followed." Beware of imitations.

THE GERMAN emigrants outnumber the Irish two to one every year.

LONG FIBRE.—The longest continuous fibre known at the present time is that of silk. A cocoon of a well fed silk worm will often yield 1,000 yards long, and in one instance one has been produced which contained 1,295 yards without a break.

Buffalo Lithia Water, Spring No. 2, in Bright's Disease, Gout, Stone in the Bladder, and Diseases Generally of Uric Acid Diathesis, Etc., Etc.

DR. WM. A. HAMMOND, of Washington, D. C., Surgeon General U. S. Army (retired), Professor of Diseases of the Mind and Nervous System in the University of New York, etc.

"I have for some time made use of the BUFFALO LITHIA WATER in cases of AFFECTIONS of the NERVOUS SYSTEM, complicated with BRIGHT'S DISEASE OF THE KIDNEYS or with a GOUTY DIATHESIS. *The results have been eminently satisfactory.* Lithia has for many years *been a favorite with me in like cases, but the* BUFFALO WATER CERTAINLY ACTS BETTER THAN ANY EXTEMPORANEOUS SOLUTION of THE LITHIA SALTS, and is, moreover, better borne by the stomach. I also often prescribe it in those cases of CEREBRAL HYPERÆMIA resulting from OVER MENTAL WORK—in which the condition called NERVOUS DYSPEPSIA exists—*and generally with* MARKED BENEFIT."

DR. WM. B. TOWLES, Professor of Anatomy and Materia Medica, in the Medical Department of the University of Virginia:

"BUFFALO LITHIA SPRINGS, No. 2, belongs to the ALKALINE or, *perhaps, to the* ALKALINE SALINE Class, *for it has proved far more efficacious in many diseased conditions than any of the simple* ALKALINE waters.

"*I feel no hesitancy whatever in saying that in* GOUT, RHEUMATIC GOUT, RHEUMATISM, STONE *in the* BLADDER, and in all diseases of URIC ACID DIATHESIS, *I know of no remedy at all comparable to it.*

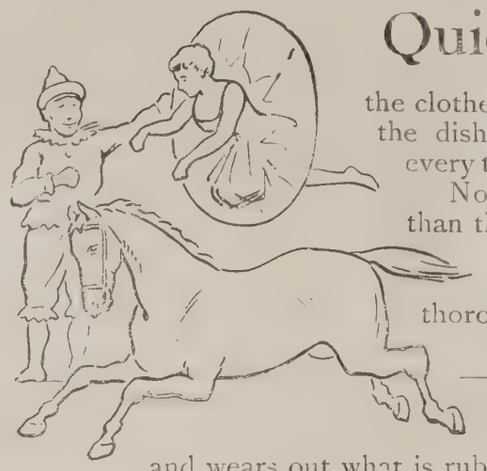
"*Its effects are marked in causing a disappearance of* ALBUMEN *from the urine. In a* single case of BRIGHT'S DISEASE *of the* KIDNEYS, I witnessed *decided beneficial results from its use, and from its action in this case I should have great confidence in it as a remedy in certain stages of this disease.* In DYSPEPSIA, especially that form of it in which there *is an excessive precaution of* ACID *during the process of nutrition*, in some of the PECULIAR AFFECTIONS *of* WOMEN, notably in SUPPRESSION of the MENSES, and in CHRONIC MALARIAL POISONING, etc., I have found it highly efficacious."

DR. G. HALSTEAD BOYLAND, late Professor of Surgery, Baltimore Medical College, late Surgeon French Army (Decorated), Member Baltimore Academy of Medicine, Member of American Medical Association.

"In BRIGHT'S DISEASE of the KIDNEYS, ACUTE or CHRONIC, BUFFALO LITHIA WATER, Spring No. 2, is, in my experience, *without a rival*, whether in the PARENCHYMATOUS form or INTERSTITIAL NEPHRITIS. In cases in which the ALBUMEN in the URINE reached as high as 50 per cent., I have known it under a course of this water gradually diminish and finally disappear, at the same time other alarming symptoms were relieved and the sufferers restored to health.

"In STONE in the BLADDER of the RED LITHIC ACID and the WHITE PHOSPHATIC DEPOSIT, the SOLVENT power of this water is *unmistakable*."

Water in cases of one dozen half gallon bottles, $5.00 f. o. b. here.



THOS. F. GOODE, Proprietor, BUFFALO LITHIA SPRINGS, VA.

TOBACCO PIPE.—Although tobacco had been introduced into Europe by Sir Walter Raleigh over a century before, it was not until 1690 that the tobacco pipe, in its form as we now know it, was introduced. Its inventor was Johann Franz Jacob Villarius. Before that date tobacco was smoked from clay cylinders.

VELOCITIES OF THE EARTH.—The earth travels in its orbit around the sun at an average pace of about nineteen miles a second. Owing to the revolution around its own axis a point on the surface of the earth at the equator travels at the rate of seventeen miles a minute, and in our latitudes about eleven miles a minute.

RAILROAD TIES.—According to good authority, $100 a mile of railroad track a year is saved the railroad companies by treating, chemically, the wood of which the ties are made, before laying them. The average life of an untreated tie is one to four years, while by the process it may be increased to ten or fifteen.

MANUFACTURED EGGS.—The contribution which the hen makes to breakfast possibilities would seem hard to imitate, yet it is freely stated in English journals that the industry of manufacturing eggs has attained large dimensions in that country, and further that the manufactured article is for most purposes as good as the genuine.

Quick as a wink

the clothes are washed, the paint scoured, the dishes washed, the house itself and every thing in it made bright and clean. Not with soap—you know better than that. But with Pyle's *Pearline*. Dirt leaves, and the work is done—easily, quickly, safely, thoroughly.

You save time with *Pearline*—but you save more than that. You're spared the endless rub, rub, rubbing, that tires you out and wears out what is rubbed.

It's money in your pocket to use *Pearline*. If it cost more than soap if it were dangerous—then you might hesitate. But you needn't. It's as cheap as any soap, and just as harmless.

Beware Peddlers and some unscrupulous grocers will tell you, "this is as good as" or "the same as Pearline." IT'S FALSE—Pearline is never peddled, and if your grocer sends you something in place of Pearline, do the honest thing—*send it back*. 244 JAMES PYLE, New York.

ORIGINAL. No. 67.

Flannel Cakes.

BY NELLIE CAMPBELL BEDFORD.

Four cups flour; one-half cup white corn meal; four eggs; one tablespoonful butter, melted; two cups milk; one teaspoonful salt; two level teaspoonfuls Cleveland's Baking Powder. Beat the yolks and whites of the eggs separately. Mix the flour, meal, salt and baking powder, add the milk, egg yolks and melted butter and beat hard. Stir in the stiffly beaten whites and bake on a hot griddle.

Use only Cleveland's baking powder, the proportions are made for that.

If cake dries out, gets husky, crumbly, or tasteless like bakers' bread, it isn't bad luck but bad baking powder.

Cake *keeps* moist, *keeps* its natural flavor when made with Cleveland's Baking Powder. One special excellence of Cleveland's.

CUTTING SHINGLES.—A new machine for cutting shingles is described as cutting 96,000 in a ten hours run. The wood is steamed for five hours before being placed under a knife that runs at 170 strokes a minute, at which rate the shingles are cut smooth and ready for treatment in the ordinary course. The steaming drives the sap out of the wood and prevents warping.

DAKOTA WHEAT.—Some interesting details of Dakota's phenomenal crops are in the form of accounts of big yields on individual farms. One farmer in North Dakota thrashed out 1,034 bushels of wheat from thirty-three acres of land—a little more than thirty-one bushels to the acre—and he netted $858 20 on his crop. Rolette County claims yields of forty bushels of wheat to the acre, seventy-five bushels of oats, sixty bushels of barley, and 500 bushels of potatoes. Yields of twenty-one to thirty bushels of wheat to the acre are common. One man has 700 acres of wheat giving thirty bushels to the acre. And the farmers are receiving eighty to eighty-three cents a bushel for their wheat.

INGENIOUS MEASURE.—An ingenious instrument, by means of which the profile of a river-bed can be taken automatically from a boat at the rate of 3¾ to 6¼ miles an hour, has been invented by a German engineer, Mr. Stechner. The apparatus consists of a curved arm, which is hinged at its upper extremity and is so long that the lower curved portion trails on the bottom of the stream. Of course, the deeper the stream the greater the inclination of the arm, and hence, by a suitable recording mechanism, the depth can be automatically registered in a revolving drum as the boat proceeds on its course. The instrument has been practically tested on the Elbe, where soundings were made over a distance of 297 miles in ten days.

IMPROVED BRICK.—It is found that a very superior quality of brick may be manufactured from the waste sand employed at the factories in grinding and polishing plate glass. The grinding of plate glass is accomplished by means of wooden plates covered with iron, between which quartz sand abundantly moistened with water is brought. By this manipulation of grinding, consisting in a constant moving to and fro of the grinding plate over the plate to be ground, the quartz sand becomes mixed with particles of iron and sand, and after losing its sharpness is cast aside as waste. This sand contains about fifteen per cent. of glass particles and two per cent. of iron, is very hygroscopic, and, before it can be used for making bricks, is dried, and then pressed into the mould under a pressure of 660 pounds per 0.155 square inch, the pieces thus obtained being subjected to a temperature of 2,732 deg. F., at which temperature the glass enters into a combination with the sand, a new product with new properties being the result. The bricks thus produced have a specific gravity of only 1.5 and are perfectly white, and, as they are not attacked by acids, are considered to be especially desirable for use in factories of chemical products, particularly in those of sulphuric acid. They also resist frost, and, as shown by experiment, they possess a compressive strength of from 840 to 975 pounds per 0.155 square inch.

ESTABLISHED IN LONDON, 1831.

DEAN'S PATENT Ardenter Mustard

This Mustard is Superior to any manufactured both for table and sick room

GRANT.

SHERMAN.

SHERIDAN.

McCLELLAN.

GEN. GRANT'S MEMOIRS.

Original $7 Edition for 30 Cents.

NO book, excepting the Bible, has ever had such a sale in the United States as General Grant's Memoirs. 650,000 copies have already gone into the homes of the rich, but the subscription price of $7.00 has placed it beyond the reach of people in moderate circumstances. **If 650,000 people have been willing to pay $7.00 for Grant's Memoirs, there must be a couple of million people in the United States who want them, and will jump at the opportunity** to buy them at the low figure here offered.

We will send you General Grant's Memoirs, publisher's original edition, best paper, cloth, green and gold binding, hitherto sold by subscription at $7.00,

FOR 30 CENTS!—FOR 30 CENTS!—ABSOLUTELY ONLY 30 CENTS!

and absolutely a proposition such as has never been made in the history of book publishing. The two splendid volumes of Grant's Memoirs, of which 650,000 copies have been already sold—not a cheap edition, but the best—for 30 cents; provided you send your subscription of $1.00 to the **AMERICAN ANALYST** one year, and also a subscription of $3.00 for the **COSMOPOLITAN MAGAZINE,** the brightest and cheapest of the great illustrated monthlies, itself equal to the best $4.00 magazine.

The **COSMOPOLITAN** is enabled to make this offer because of **the purchase of 600,000 volumes at a price which even publishers would deem impossible, and with the idea of running up its circulation to half a million copies.** By contract with the **COSMOPOLITAN,** and at no profit to us, we are enabled to offer our readers a share in the low price obtained through the largest purchase of books ever made in the history of the world.

If, however, you have Grant's books, our offer will permit you to take instead,

GEN. SHERMAN'S MEMOIRS, 2 Vols., sold by subscription for $5.00
GEN. SHERIDAN'S MEMOIRS, 2 Vols., sold by subscription for 6.00
GEN. McCLELLAN'S MEMOIRS, sold by subscription for . . 3.75

All of these are bound in cloth, green and gold, in uniform style with Grant's Memoirs.

Send us at once $3.00 for year's subscription to the **COSMOPOLITAN,** $1.00 for year's subscription to the **AMERICAN ANALYST,** and 30 cents for a set of Memoirs—$4.30 in all—to which add postage on the particular set of Memoirs selected.

WHY DO WE MAKE THESE GRAND OFFERS?

Simply because we want every intelligent family to keep well informed as to the popular science of this progressive era. We publish the **only popular journal on this subject—THE AMERICAN ANALYST.** Its subscription list is already very large; but we want at least **Fifty Thousand additional subscribers before January 1, 1892.** We know that, if we shall get them, we shall be able to hold most of them as permanent readers of our periodical. So at present sacrifice and at great cost, we have entered into a combination. The **COSMOPOLITAN** is the brightest and cheapest of the great illustrated monthly magazines; it gives annually 1,536 pages by the ablest writers, and over 1,200 illustrations by the ablest artists; and is just as interesting to the young boy or girl as to the oldest grey head. Now, then, we ask you to send us merely $4.30, and, on receipt of same, we will mail them to you regularly for **one year,** and will also send you (making no charge for the books) a set of **GENERAL GRANT'S MEMOIRS,** or either of the other works that you may select. **NO SUCH OFFER AS THIS WAS EVER MADE BEFORE BY ANY PUBLISHER SINCE TIME BEGAN!**

UNLESS OTHERWISE DIRECTED,

we shall invariably ship the books by express, charges to be paid by the receiver. If you wish the volumes forwarded by mail, you must distinctly say so at the time when you send us your address and the Money; and you must also enclose postage to prepay the packages at the following rates: **GRANT'S MEMOIRS,** 96 ozs., 48c.; **SHERMAN'S MEMOIRS,** 92 ozs., 46c.; **SHERIDAN'S MEMOIRS,** 84 ozs., 42c.; **McCLELLAN'S MEMOIRS,** 48 ozs., 24c. The government rate for postage on books is one-half cent per ounce. The **COSMOPOLITAN** and **AMERICAN ANALYST** are sent to subscribers free of postage.

TABASCO PEPPER SAUCE,

OR LIQUID PEPPER.

Is simply the Pulp of the Ripe Pepper Extracted by Pressure.

The seed of this Pepper was obtained from Central America, and by careful cultivation in Louisiana for many years has been so improved in strength, flavor and aroma, as to have become a new variety of Red Pepper, superior to all others. The pulp is so handled as to retain all the flavor, strength, aroma and color of the ripe fruit, and to keep unimpaired in any climate. It excites the appetite, promotes digestion, and is pronounced by connoisseurs to be the finest condiment in the world. For medicinal purposes it recommends itself by its purity, strength and diffusible form.

Manufactured by E. McILHENNY'S SON,

WASHINGTON DETECTIVE AGENCY,
Box 787. Washington, Iowa.

DO YOU KNOW THE DANGER OF USING SOAP?

We do not mean soap made from proper material; and when we tell you that about ninety-nine per cent. of Toilet Soap is made from refuse fats gathered from tenement houses, hospitals, butcher shops, and from cattle dying of disease or during transportation, you will, we believe stop and think. Putrefactive changes have taken place in most of this material, as it is mixed with lean meat, blood, bones, sinews, etc. There is at least *one* soap that is made wholly from vegetable material—OLIVE and PALM OILS—and that is

VELVET SKIN SOAP.

It will keep the skin soft and in a healthy condition, as no animal fats are used in its manufacture. Nothing in one's personal outfit is quite so satisfactory as a thoroughly reliable Toilet Soap. We are confident that a trial of this article will insure its continued use. If the dealer does not keep it, do not take any other, but require him to order it for you, which he can do readily. **Otherwise, send to us direct.**

THE QUEEN'S PRIZE SCHOOL OF HISTORY.

About two years ago the publishers of THE CANADIAN QUEEN added what has proven to be a very popular and successful feature to their publication in establishing their Prize History School. It has offered competitive examinations in English, Canadian and American History, giving valuable rewards to those making the most correct answers. During this time there have been added the names of over forty thousand new subscribers to their books. Rewards have been made by THE QUEEN which have cost them in cash over ten thousand dollars. THE QUEEN'S Prize School of History has received the sanction and support of the clergy, press, and, in fact, of the best people of the Dominion of Canada. The following, taken from a leading daily newspaper, expresses an opinion which is universal:

A HANDSOME PRIZE.

AN EVIDENCE OF WHAT A GENUINE MAGAZINE COMPETITION OFFERS.

"On Friday there arrived from Toronto, for Miss M. Hora, a handsome Shetland pony, harness and cart, being the first award in the Royal Quilt Competition of THE CANADIAN QUEEN magazine. It attests the genuine nature of the magazine's contests by its excellent condition and value. THE QUEEN has frequent competitions and has made innumerable awards, displaying a generosity quite surprising to those who have had experience of the limited field for Canadian journalistic enterprise. But THE QUEEN has been a success as a business venture from the start, and is growing in literary excellence steadily. It covers the field of fashion, as well as light reading; talks to the household, the young, and, indeed, all home classes. The competitions have been used to assist the introduction of the magazine, for where it is introduced it is quite certain to remain a monthly guest. The leading prizes have been made, as instance this latest to Kingston, while many smaller prizes have rewarded the moderately successful among competitors. THE CANADIAN QUEEN is truly royal in its ways."—*The (Kingston, Ont.) Daily British Whig*, June 27th, 1891.

QUESTIONS IN AMERICAN HISTORY.

1.—Give the names of the early navigators who it is claimed by historians first discovered America.
2.—From whom has America taken its name?
3.—What class and nationality first settled Virginia? New York? Massachusetts? Pennsylvania? Maryland?
4.—What action did the Continental Congress of 1774 take and what was the result of that action?
5.—What was the first battle fought in the War of the Revolution?
6.—What nation rendered the Americans great assistance in the War of the Revolution?
7.—Give the names of the committee appointed to draft the famous Declaration of Independence.
8.—What was the date of the signing of the United States Constitution?
9.—After becoming a nation and before the great Civil War, what were the principal conflicts which engaged the Americans?
10.—What was the direct cause of the Civil War? What Generals of the Northern Army have occupied executive positions under the Federal Government since the closing of the War? Who was Commander-in-Chief and who were the principal Generals of the Confederate Army during the struggle?
11.—How long did this War last and what is the computed loss of life?
12.—What can be said to day of the United States as a nation?

To the *First* gentleman sending the correct answers to the above questions in American History the publishers of THE QUEEN will present **"Majestic"** acknowledged the **Handsomest and Finest Riding Horse in Ontario.** ("Majestic" is sixteen hands high, thoroughbred, seven years old, and valued at $350.00.) To the *First* lady the publishers of THE QUEEN will present an elegant **Jacket of Genuine Alaska Seal** to be made according to the measurement supplied by the winner. To the *First* boy under sixteen years of age the publishers of THE QUEEN will present a **Little Giant Safety Bicycle** valued at $75.00. To the *First* girl under sixteen years of age the publishers of THE QUEEN will present an elegant **Music Box,** playing twenty tunes, finely finished and valued at $55.00.

To the gentleman from whom the *Last* correct answers are received before the close of this Competition, the publishers of THE QUEEN will present a **First Cabin Passage to Europe and Return** and **$200 in Gold** for expenses. This trip can be taken by the winner any time before October 1st, 1892. To the lady from whom the *Last* correct answers are received before the close of this Competition the publishers of THE QUEEN will present a **Pony, Cart and Harness.** To the boy under sixteen years of age from whom the *Last* correct answers are received before the close of this Competition the publishers of THE QUEEN will present a **Solid Gold Watch** containing one of the best American movements, and valued at $75.00. To the girl under sixteen years of age from whom the *Last* correct answers are received before the close of this Competition the publishers of THE QUEEN will present an elegant **Solid Gold Watch,** containing one of the best American movements, and valued at $65.00.

ADDITIONAL PRIZES IN ORDER OF MERIT: Silver Tea Services, Ladies' Gold Watches, Silk Dress Patterns, French Mantel Clocks, Portiere Curtains, Toilet Cases, Manicure Sets, and many other useful and valuable articles.

The object of the publishers in offering these liberal prizes is to introduce THE QUEEN Magazine into **new** homes. Answers must be mailed *on or before* November 10th, 1891, and must be accompanied by $1.00 for one year's subscription to THE CANADIAN QUEEN. Prizes awarded to subscribers residing in the United States will be shipped to them **free of duty.** The distribution of awards is in the hands of disinterested persons, and decisions will be based on the correctness of answers. Use your own language in wording the answers. No corrections can be made after your answers are mailed. THE QUEEN is a large, forty-eight page family magazine, especially interesting to ladies and children, and visits regularly **over one hundred thousand of the best homes** in Canada and the United States. The awards in THE QUEEN'S Prize School of History are made strictly with regard to merit, without partiality to persons or locality. The decisions must be accepted as final. If you have never seen a copy of THE QUEEN send six U. S. two cent stamps and receive a late number, post paid, containing letters from those who have received rewards in previous contests.

Address THE CANADIAN QUEEN, PRIZE SCHOOL OF HISTORY, 58 BAY STREET, TORONTO, CANADA.

PREHISTORIC RELICS.

The Archæological Association, which is under the auspices of the University of Pennsylvania, is about to set on foot original explorations in parts of the United States which have not been carefully examined in respect of their prehistoric relics. Several men, who are experts in this kind of scientific work, will be placed in the field. During the summer of 1891 the association has thoroughly explored a number of ancient village sites in the valley of the Delaware, and the work has thrown new light on the customs and condition of the prehistoric Indians. On an island in the Delaware an implement maker's workshop was found, and in another place were 116 finely chipped knives, averaging about six inches in length. The quarry of jasper, where the Indians got their raw material, was found, and thousands of specimens of their workmanship were secured.

SANITARY TRIUMPHS.

In an interesting article in the June issue of the American Statistical Association's quarterly publication, we find some significant facts regarding the advantages of sanitary legislation experienced in England within the past sixteen years. In the year 1875 a general law was passed in England for the protection of the public health, known as the Public Health Act, and from that time the death rate in England has decreased for all diseases which owe their origin and growth to defective drainage and impure water supply. Typhoid fever is such a disease, and the diminution of 57 per cent. in the death rate from this malady is undoubtedly the greatest triumph for sanitary reformers. During the ten years from 1866 to 1875 the average annual mortality was 22.19 per thousand inhabitants; and from 1838, the first year of careful registration, to 1865, the average annual rate was about 22.35 per thousand. But for the ten years of the period 1880 to 1889 the average falls to 19.08. It seems justifiable to ascribe this diminution in the death rate to the operation of the Public Health Act, and the execution of duties such as drainage, inspection of water-supplies, vaccination, and others which are becoming better understood. Mr. Farr, in his *Vital Statistics*, estimates the value of human life in England to be about $770 a head; that is, the value inherent in the people as a productive money-earning race. If we suppose, which is allowable if other things remain the same, that this diminution of the death rate during this last decade was due to the measures taken to that end, we find that the number of lives saved, representing a total for the decade of 856,804 persons, according to Mr. Farr's estimate represents a social capital of $650,000,000. Thus, in ten years the country has more than regained the sum that was spent in sanitary improvements in the fifteen years, and in this calculation nothing figures for spared grief, better health and happier life. This diminution of mortality is not observed in all forms of disease. The mortality from zymotic diseases, from 1861 to 1870, was 42.54 per 10,000 living, and this was reduced to 24.52 in the period from 1880 to 1889, but measles, diphtheria, and whooping-cough appear to have escaped the influence of sanitary measures. Consumption has equally diminished in England in these last years. The mortality from this cause in the years 1861 to 1870 was 24.89 per 10,000 living. For the period 1880 to 1889, it fell to 17.36. The statistics further demonstrate that sanitary measures affect the death rate of young persons between the ages of one and twenty-five years, and especially between ten and twenty years. The gain in this latter decade, which amounts to 28 per cent., is economically a great gain. The death rate for old persons has increased during the last decade, a fact which may be chargeable to the bustle of the nineteenth century, the wear and tear upon the nervous system, while the effect of sanitary improvement is most noticeable in the abatement of infant mortality.

AMERICAN ALUMINUM ABROAD.

The German Government has recently placed an order in the hands of its agents in the United States for a large quantity of pure aluminum for army purposes. This order calls for eighty-five tons of the metal. The amount placed in the hands of the agents is $110,000. As yet the order has not been accepted, and probably will not be for some time. There are only two companies in this country—one in Lockport N. Y., and one in Pittsburg, Pa. Neither can accept the order, or part of it, because of a gigantic patent litigation which is now being waged between them, and the probability is that the German Goverment will have to wait some time before they can secure the metal. This metal will be turned into buttons, buckles, and for field purposes, such as wire for telegraphic and telephone services and cartridge shells, it having been proved that aluminum will withstand the corrosive action of the new smokeless powder which has come into universal use in Europe lately. It is also to go into a certain newly invented pontoon bridge, its great lightness especially commending it for this purpose.

UNEARNED CITIZENSHIP.

We have had occasion heretofore to discuss the manner in which the privileges of American citizenship are often perverted and abused by that class of foreigners who, through the force of early association or inborn prejudice, are incapable of appreciating their real worth and purpose. A case recently occurred in Wisconsin that fairly illustrates one phase of this subject. A German, fifty years of age, applied to a court in that State for naturalization papers. It appeared that he had come to this country when a young man, had lived in Wisconsin twenty-five years, and had amassed the snug fortune of more than one quarter of a million dollars. He had never before sought to be made a citizen; he never cared to vote; he was all the time absorbed in the greed of wealth; the lust of gold was his dominant passion. He had never married—had no home except as a bachelor, no binding ties of any kind. He was rich beyond his own expectations, had converted all his wealth into money and bonds, and his purpose was to return to Germany, there to abide the remainder of his days. His only object in seeking American citizenship, with naturalization papers to show, was that he would thereby be exempt from the obligations which Germany exacts of her born subjects in military service and otherwise. He had no intention of exercising the privileges of citizenship in the United States, as a voter or in any capacity; no purpose of remaining in America. He had witnesses in court to prove his residence in Wisconsin for upward of twenty years, to testify to his moral worth and standing in the community, and to every other qualification of eligibility to citizenship. But he had himself stated to the presiding judge the purpose of his action and it determined the application against him. The Court

READ PAGE 501.

held that a man who had for so long a time neglected his opportunity, and now sought citizenship solely as American protection, and exemption from the duties of his native land, to which he intended to return to pass the remainder of his life, was unworthy of the sacred investiture, not at all fitted for citizenship, and denied his application. The Court ruled rightly. Such should be the ruling in every case of the kind. In return for the endowment of American citizenship the individual incurs obligations and duties which should be observed and performed. The precious boon to the alien born is not conferred simply to gratify selfish motives, and assure protection abroad.

AMERICAN PUBLIC HEALTH ASSOCIATION.

The 19th annual meeting of the American Public Health Association will be held at Kansas City, Missouri, October 20th to the 24th, 1891. The Local Committee of Arrangements announces that all the Railway Passenger Associations of the country, have granted a one and one-third fare rate on the usual certificate plan, for the round trip that is: delegates will procure a certificate of attendance from the agent at the starting point by paying full fare to Kansas City. On their arrival they will have the certificate of attendance signed by the proper officer of the Association at Kansas City. This certificate will then procure return ticket for one-third fare. All the leading hotels of Kansas City will give special rates to delegates. Arrangements have been made for an excursion into Kansas, as one of the features of the entertainment of the Asssociation.

NEW AIR SHIP.

A BALLOON THAT GENERATES ITS OWN GAS.

Other parts of the world as well as the United States have new projects for the navigation of the air. Henri Lecomte, Director of the School of Aerostation at Paris, will soon make a rash attempt to cross Africa by balloon, starting from Mozambique. The peculiar feature of his balloon is a special apparatus for the production of hydrogen gas, so as to maintain the floating power. This gas is to be generated during the night time. The balloon will carry provisions for 100 days, and will have a capacity of 10,000 cubic metres. Experienced aeronauts believe that this is a very hazardous undertaking. Lecomte proposes to cross Africa in its widest part, making a longer journey than any yet recorded. If an accident occurs to his air ship, his chances for reaching civilization are about as slim as they would be if he descended in the middle of the Atlantic, for if compelled to abandon his balloon he is almost certain to find himself in a savage wilderness, hundreds of miles from succor, and very likely among hostile natives. Mr. Maxim, the inventor of the Maxim gun, is now completing his invention of an aerial machine which he asserts will be superior to all other agencies of destruction in warfare. He has already spent $50,000 on his invention, and if necessary $50,000 more will be expended to insure success. The machine is building at Crayford, near London, and is nearly ready for a practical trial. Maxim has made an exhaustive series of experiments to test the practicability of his idea, and it remains to be seen whether he can carry out his scheme with a full-sized machine. He says his invention has been recently tested while captive, the engine propelling it being at work, and he thinks he proved to be capable of carrying at least 10,000 pounds. The weight of the full-size machine, including men, engines, fuel, water and all accessories is 5,400 pounds. The fuel is gasoline, giving 5,000 gas jets. The machine is propelled by two screws, and there is an engine to each screw. Maxim obtains buoyancy by the pressure of the air on the under side of sundry planes inclined upward, this pressure being due to the forward motion of the machine as it is driven by the propeller. He expects that the machine will actually lift itself from the earth. The men who first navigate it will undoubtedly incur great risk, if indeed they can get it above the earth at all. Mr. Brearey, who has made air machines a study, says that the working data for Maxim's machine can be obtained only by free flight. "We cannot, therefore," he says, "expect success at the outset." As yet everything is purely tentative, and Maxim's friends can only hope that he is on the right track. His idea is that, with such a machine, destructive projectiles can be hurled down upon an enemy with annihilating results. Those who know what his intention is say he has at least devised a lighter motor than has been previously invented for use in air machines.

HISTORIC WATCHES.

HOW JEWELRY SOMETIMES IS ASSOCIATED WITH ROMANCE.

The watch of King Jerome had a parallel in the watch of King Leopold I., says a Paris correspondent. That timepiece was in repousse gold and girdled in brilliants. It had also the cipher in those gems on a shield on the back of L. S. C. The taste shown in the design was not irreproachable. Who was there in the art world in London, in the time of the Prince Regent, whose taste was not as bad as it could be, Sir Thomas Lawrence excepted? and he was in a degree infected, and thought more of the belongings of the fair ladies who sat to him than of the sitters. Well, to return to the watch. If it was not beautiful in design it was very costly, and was the gift of the Princess Charlotte of Wales. She died before she had been a year a wife. The widower was not to be consoled for her loss, though always seeking consolation. Caroline Bauer, in her memoirs, speaks of his attempts to find it. If Mary Anne Smith or Baroness Meyer had scribbled their recollections for the printers, they might also have told some curious tales. Leopold erected, in the shape of a round Greek temple, a mausoleum in the garden of Claremont. He gathered together there busts and portraits of his lost wife. At the end of twelve years of sentimental mourning and money saving he was called to reign over the newly created kingdom of Belgium on condition of marrying the eldest daughter of the King of the French. He thought of transporting the mausoleum to Laeken, but as the Princess Charlotte's remains belonged to England he could not do so. What he did instead was to have a kind of reliquary placed between the works of the watch and the case, in which he placed a miniature of the princess, a small painting on ivory of her tomb, a lock of her hair, and a chip of the oak coffin in which she and her dead child lay. When Leopold married, the Queen of the Belgians noticed that he was always contemplating his watch when he sat in his study. As the palace was rich in clocks, she could not divine why he so often gazed on the watch which he always wore. Directly she came upon him when he was thus engaged he shut up the watch and pocketed it. He was a cold, distant man, and never allowed her to talk playfully to him. Her curiosity naturally grew very keen to know why the watch had such great attractions for him, but she only discovered it during one of his illnesses, when she got the watch, and, forcing a secret spring, found there the image of her predecessor. The countenance of the Princess Charlotte was a lovable one, and she had plastic beauty. Queen Louise was taken with a fever of retrospective jealousy so strong that she lost all self-control. She confessed to Leopold her misery. He asked her how dared she meddle with souvenirs which he held sacred, and refused to be nursed by her. When he recovered, he told her that she had estranged herself forever from him by her impertinent prying. Their eldest child died, and no reconciliation followed his death. Leopold seriously contemplated getting the Belgian Chambers to nominate his nephew, Duke Augustus of Saxe-Coburg, to succeed him. This plan was put an end to by the intervention of Louis Philippe, who informed his son-in-law that France would not suffer him to carry it out, and Talleyrand was sent to Brussels to bring together the virtually separated royal pair. He was able to do so. But the queen, when dying, in 1851, said that from the day she forced the secret spring of the watch she always felt as though the corpse of the Princess Charlotte lay between herself and Leopold. In sign of repentance at her too demonstrative jealousy she called her eldest daughter, the now insane Empress Charlotte of Mexico, after the first wife of Leopold. The watch of Jerome Bonaparte, King of Westphalia, was made on the same system as that of Leopold, but of exquisite workmanship. Jerome was one of the most dissipated men of his time, and as fond of baccarat as the present Prince of Wales. When, after his imperial brother was transported to St. Helena, he had gambled away his money, he staked rings, pins, and snuff boxes. One night, as he was playing at the house of Fenzi, the banker at Florence, he threw his watch on the table, having nothing else to stake. His wife was standing by, and boldly taking it up proceeded to examine it. "I beg you not to open it," cried Jerome. This excited the curiosity of Queen Catherine, and she insisted upon seeing what was inside. Her erring husband, for whom her fondness was extreme, pushed a spring, and a most beauteous young face appeared. Catherine burst into tears, and insisted on being told who the fair original of the miniature was. "Since you must know," cried Jerome, "It's my wife, Elizabeth Paterson, whom the Emperor made me leave to marry you!" Were not these watches like the mysterious chamber in Bluebeard's castle? and were not the consequences of seeking to know what they hid almost as bad as those which befell Bluebeard's wife for peering into the room which she was not to open? The ex-imperial family of Brazil has received the good news that all the jewels classed as private property of Dom Pedro and his late wife would be delivered over to him. Those bought by the nation at the time of his marriage, to be given to his bride, are excepted; so is the crown, which was made in London, the sceptre, and the imperial mantle. The jewels of the Crown Princess, which were bought for her in pursuance of a vote of the Brazil Parliament, which granted her a dowry, are declared national property. But they are of far less value than those owned by her father and mother. Dom Pedro and his wife had the finest collection of Brazilian diamonds, perhaps, in the world. They will doubtless soon come into the market, the Emperor being heavily in debt, and his income having altogether fallen off. The Cronstadt fetes have made everything Russian the fashion. Shops are being opened on and near the Boulevard, in the windows of which Russian orfevriere and plate are on sale. The teaspoons are so enamelled in bright colors as really to merit being classed with jewelry. As much may be said for egg cups, tankards, cruet stands, and hand mirrors. If the French take up this style, they will go a long way in giving it a stamp of higher beauty. I suppose the taste for bright colors evinced by Russian gold and silver smiths came at no far back period from Asia. The six months' winter, when the Czar's vast empire is under snow, must render polycrome ornaments of the breakfast and dinner tables of the wealthy extremely grateful to the eye. Richly embroidered tablecloths, also in many colors, go with them. The tones seem crude in this climate; but to visual nerves, jaded with endless stretches of white out-of-doors, they will be a pleasant stimulus.

LIFETIME OF SALOONISTS.—The average lifetime for proprietors of beer saloons is 51.35; proprietresses of beer saloons, 51.95; brewers, 42 33. Inquiry has shown that the male proprietors of wine rooms live but forty-nine years, and women who keep wine rooms but forty-seven.—*Med. Record.*

LIGHT.

THE NECESSITY OF SUNLIGHT FOR HUMAN HEALTH.

The physician who has witnessed the last hours of great men, has not much faith in the broad grasp and keen insight sometimes ascribed to their latest utterances. The necessary strength and disposition is almost invariably wanting at the moment of separation of soul and body. Goethe, too, when in his last moments he gave expression to the words with which this article is headed, had probably no thought of using them in any spiritual sense; he merely felt the shadow of death passing over his eyes and craved for "the source of sweet life," as he called the sun in one of his letters to Schiller. It is in this sense, too, that we employ his last words in the remarks which follow upon the influence of light—not upon the eye, for which one can consult the numerous works of specialists, but upon the whole organism. The influence of light upon the system has, strangely enough, not been made the subject of so much investigation as other hygeinic conditions; but it may be asserted without fear of contradiction, that not even fresh air is more necessary to our existence and well-being, and that no other agent exerts so great an influence upon the nervous system, the medium of our intellectual activity and spiritual life. From the hoariest antiquity light has been regarded as the chief life-giving and life-qualifying agency. In the Mosaic account of Creation, the fiat "Let there be light," heralded the birth of the world; and to-day we use the words "he first saw the light" to signify birth. It was reverenced by the ancient Egyptians as the supreme god of the universe, and worshipped as Ra, and also by the Persians as Ormuzd, the lord and giver of light. The Christian heaven, too, is represented as a region of light. And when one speaks of the sombre, serious outlook upon life of northern, in contradistinction to the light, joyous nature of southern races, we but indicate the influence of light in the formation of national temperament, which may be regarded as similar in effect to the contrasted conditions to which the individual is exposed. In the correspondence between Goethe and Schiller the weather forms a frequent topic of criticism. Absence of light oppresses the spirit, and renders us gloomy, creates, indeed, constitutional sickly states of mind, of which, perhaps, the most conspicuous example is the spleen among the people of foggy England Abundance of light elevates and stimulates spiritual force. "The season oppresses me as it does you," wrote Schiller, whose creative power, like Goethe's, grew feeble, if not wholly dormant, in winter. No wonder, then, that all the poets, from Sophocles down, have apostrophised the sun, the source of light, in glowing terms. Light calls into activity the healthy and best forces of the human soul, and good deeds can be done openly. Only evil deeds and evil thoughts, shrink from the light. "The dark side of human nature" is something more than a poetic expression. The want of light, exercises, with most men, a prejudicial influence on the character and direction of thought, as any one may determine by taking notes of his personal experiences. How often have physicians been told by patients, ordinarily calm and sensible, that on sleepless nights they have had to kindle a light to liberate themselves from the evil spirits of darkness, and escape the influence of their own imagination, by the aid of which they conjure up the most fantastic and distressing experiences which they cannot escape. That darkness makes the spirit sad and gloomy, is an observation frequently confirmed by oculists, who are compelled sometimes for weeks to seclude their patients from the light. There are even patients who cannot submit to this course of treatment, and who declare that it would drive them mad to submit longer to artificial darkness. In military circles, too, it is well known that imprisonment in a dark cell has additional horrors. With some people darkness creates very depressing conditions; and, on the other hand, now weaker, now stronger moods of exaltation—waking phantasies as they are called—these are for the most part gloomy; and, if by chance they invade the domain of lighter fancies, they present them only as caricatures of real joyous musings. It is further well known that darkness upsets the just estimate of time and space; minutes expand into hours, distances are greater, and the road seems interminable. Men who are bold in the light grow timid in the dark. Even with insensible sick persons, as for example with typhus patients, darkness increases the delirium or heralds its approach if it is not already present. In short, light regulates and calms mental activity; darkness perverts and excites it. Even sensation is excited and a moderate measure of pain becomes unendurable in the dark. The general facts, as above stated, have led to the conclusion that the nervous excitability and nervous energy in civilized man is due in great part to the exclusion of the light not only from the eyes but also from the skin on which it exerts a healthy action. The climate of Northern Europe would hardly favor our going back to the habits of our barbarian ancestors, but it would certainly be more conducive to the health of our children, if they lived more in the open air, and with their hands and arms and neck and shoulders exposed. And since climate and fashion combined, prescribe the wearing of clothes which preclude all light from the skin, the next important point to attend to, is to provide wide streets and for the better lighting of our dwellings. It is desirable, too, to have the houses isolated villa fashion, so that light may fall on them from all sides. The lofty flat and apartment houses in New York and Chicago are by no means conducive to health. The windows of a dwelling house should be large enough to light up every corner, and should be shaded as little as possible, except only in summer when the direct sunlight becomes painful, and carpets and hangings should be light. "The dim religious light" which so many people like to cultivate in their homes, would not keep a plant alive, and is scarcely less prejudicial to man. However, these are social fashions which the physician is powerless to remedy. He can only hope that some leader of the fashion will take up the matter and guide the fashion in the direction of improvement. This half light is especially prejudical in the sleeping rooms which should be filled with sunlight on every occasion. The beds especially should be exposed to the full light as much as possible. The Italians show their appreciation of the physiological influence of light in the popular proverb, *Dove non viene il sole, viene il medico*, which may be rendered in English:

If you won't admit the sun,
For the doctor you must run.

—*Gartenlaube, Leipzig.*

THE GRIP.

A DIAGNOSIS THAT SUGGESTS FAMILIAR SYMPTOMS.

A writer in the *Western Medical Reporter* facetiously writes: Nature with a lavish hand has endowed the human body with no less than s'teen million of spots to which an ache or pain can be attached. When each one of these spots, both inside and out, is filled with a hard platinum tipped pain; when your head aches so that you are conscious of all the ruffles and scallops on your brain, just as you see them in the pictures in your physiology; when your heart thumps and your stomach wobbles and you have the feeling that something is wallowing through your inside works; when your sternum feels stove-in, and there is an uneasiness under your shoulder blades as though your wings were beginning to sprout; when you are one moment alive to the finger tips with thinking of the things you must get up and do, and the next completely exhausted by even the thought of doing them; when your backbone has the sensation of being twisted by a monkey wrench; when you are so dizzy that you can't see, and your ears ring and eyes water and your nose is in such a state that it is presumption to lay aside your handkerchief for one short minute; when you cough and sneeze and groan in turn—in fine, when you feel like the very deuce—you can set it down that you have the grip.

LOCAL DEFINITION.—Tommy: "What is a hold-over Senator?"—Mr. Fig: "The qualifications of a hold-over Senator vary in different States. In Kentucky he is expected to hold over half a gallon without staggering."

STERN DISCRIMINATION.—George: "Yes, sir; I cannot tell a lie—I did it."—Washington Senior: "Well, that's all right about the lie, but (whack!) d'ye think (whack!) you can tell a cherry-tree (whack! whack!) next time?"

HAD NO CHANCE.—"Your husband," said the caller, sympathizingly, "was a man of many excellent qualities." "Yes," sighed the widow. "He was a good man. Everybody says so. I wasn't much acquainted with him myself. He belonged to six lodges."

ALPINE GLACIERS.—A recent survey has established the number of glaciers in the alps at 1,255, of which 249 have a length of more than 4¾ miles each. The French Alps contain 144 glaciers, those of Italy 78, Switzerland 471 and Austria 462.

FUTURE MOTORS.—Professor Thurston says: "The assumption seems fair that the locomotive engine will have been superseded when we double our speeds, and that we must find ways to utilize the weights of the cars themselves for adhesion and to make each to carry its own motor."

SELECTING MELONS.—It is quite an art to select a choice melon without cutting a small hole through its fat green sides, but it can be done; the same as an expert can tell a counterfeit from a genuine bill—by the feeling and general appearance. The dark green of the melon should be the color of the English ivy leaves; the yellowish spot underneath caused by its contact with the earth should be tested with the pressure of the finger. The spot should have a springy resistance, and the indentation thus made should not be noticeable when the finger is removed. If it remains the melon is too ripe and likely to be watery. If no depression can be made the melon is not ripe enough.

ENORMOUS MICROSCOPE.—The Poeller Physical Optical Institute, of Munich, have under construction an enormous microscope for exhibition at Chicago in 1893. It will magnify to 16,000 diameters, or, as ordinarily fitted, to 11,000 diameters. An electric light of 11,000 candle-power is to be used for illuminating the image, which is to be projected on a screen. As the heat from this powerful light would derange the focus by expansion of the metal, an ingenious device is used to cool the metal. This is a small copper cylinder filled with liquid carbonic acid under a pressure of 350 pounds to the square inch. It is connected with the microscope in such a manner that an electric regulator automatically opens a valve and allows a drop of the acid to escape in a spray on the metal to be cooled. The liquid immediately evaporates and produces intense cold. The whole cost of the instrument is said to be nearly $10,000.—*Scientific American.*

LUNAR LANDSCAPES.—The effect of the absence of an atmosphere on the moon is that there are none of the finer gradations of light in lunar landscapes which make our terrestrial scenes so soft and pleasing to the eye. On the moon an object is either bathed in intense sunlight or else is invisible in the blackness of night. Shadows are absolutely black, and objects in the shade are not visible. Stars shine in a black sky, and are not dimmed when the sun rises above the lunar horizon. The sun must be a glorious object, his corona and the red hydrogen flames must be clearly shown and sharply defined against the black sky. Myriads of stars that are invisible in our atmosphere-obscured skies must be visible there. Intense silence reigns supreme. The rocks in sunlight must be so hot that water would hiss if transported thither and dropped on them, while those in the shade must be as icy cold as space itself. The picture which the conditions that obtain on the moon conjure up is one of absolute and awful desolation.

BRIGHT STORIES.

A MYSTERIOUS GUEST.

From the French of Honore de Balzac.

(*Concluded from page* 485.)

The merchant summoned up all the keenness which he had formerly employed in his commercial affairs. He gave the Countess the most prudent and sagacious directions, and after having agreed together as to everything they both were to say and do, the old man invented a plausible pretext for visiting all the principal houses of Carentan. He announced in each that he had just seen Madame de Dey, and that she would hold her reception that evening, in spite of her indisposition. In the cross-examination which each family subjected him to on the nature of the Countess's malady, his keenness was a match for the shrewd Normans. He managed to start on the wrong track almost every one who busied themselves with this mysterious affair. His first visit did wonders; it was to an old lady who suffered from gout. To her he related that Madame de Dey had almost died from an attack of gout on the stomach, and went on to say that the famous Tronchin having formerly prescribed, on a similar occasion, the skin of a hare flayed alive to be laid on the chest, and for the patient to lie on bed without stirring; the Countess, who was in imminent danger two days before, after having scrupulously carried out Tronchin's extraordinary prescription, now felt sufficiently convalescent to receive any one who liked to visit her that evening. This tale had an enormous success, and the doctor of Carentan, himself a royalist *in petto*, increased its effect by the earnestness with which he discussed the remedy. However, suspicion had taken too deep root in the minds of certain obstinate or philosophic persons to be entirely dissipated; so that evening the guests of Madame de Dey were eager to arrive at her house at an early hour, some to spy into her face, some out of friendship, and most from astonishment at her marvellous cure. They found the Countess sitting in her salon at the corner of the large chimney-piece.

Her room was almost as severe as the salons of Carentan, for to avoid wounding her narrow-minded guests she had denied herself the pleasures of luxury to which she had been accustomed before, and had made no changes in her house. The floor of the reception room was not even polished; she let the old dingy stuffs still hang upon the walls, still kept the country furniture, burnt tallow candles, and in fact followed the fashions of Carentan. She had adopted provincial life without shrinking from its cruelest pettinesses or its most disagreeable privations. But knowing that her guests would pardon her any expenditure conducive to their own comfort, she neglected nothing which could afford them personal enjoyment: at her house they were always sure of an excellent dinner. She even went so far as to feign avarice, to please their calculating minds, and led them on to disapprove of certain details as concessions to luxury, in order to show that she could yield with grace.

Towards seven o'clock in the evening the upper middle-class society of Carentan was assembled at her house, and formed a large circle round her hearth. The mistress of the house, supported in her trouble by the old merchant's compassionate glances, submitted with unheard-of courage to the minute questionings and stupid, frivolous talk of her guests. But at every rap of the knocker, and whenever a footstep sounded in the street, she could scarcely control her emotion. She raised discussions affecting the prosperity of the district, and such burning questions as the quality of ciders, and was so well seconded by her confidant that the company almost forgot to spy upon her, the expression of her face was so natural and her assurance so imperturbable. However, the Public Prosecutor and one of the Judges of the Revolutiunary Tribunal kept silence, watching attentively the least movement of her features, and listening, in spite of the noise, to every sound in the house. Every now and then they would ask some question calculated to embarrass her, but these she answered with admirable presence of mind. She proved how great a mother's courage can be.

After having arranged the card-tables, and settled every one to boston, reversi, or whist, Madame de Dey still remained, talking with the greatest nonchalance to some young people; she played her part like a consummate actress. Presently she led them on to ask for loto, pretended to be the only person who knew where it was, and left the room.

"*Ma pauvre Brigitte*," she cried, "I feel almost suffocated."

Her eyes were brilliant with fever and grief and impatience, as she dried the tears which started quickly from them. "He is not coming," she said, looking into the bedroom unto which she had come. "Here I can breathe and live. But in a few minutes more he will be here! for he is alive—I am certain he is alive! My heart tells me so. Do you not hear something, Brigitte? Oh, I would give the rest of my life to know whether he is in prison or walking across the country. I would give anything not to think."

She looked round once again to see if everything was in order in the room. A good fire burned brightly in the grate, the shutters were shut close, the furniture was polished until it shone again; the very way in which the bed was made was enough to prove that the Countess herself as well as Brigitte had been busy about the smallest details. Her hopes too were manifest in all the delicate care that had evidently been spent upon this room. The scent of the flowers she had placed there seemed to shed forth, mingled with their own perfume, the gracious sweetness and the chastest caresses of love. Only a mother could thus have anticipated a soldier's wants, and prepared him such complete satisfaction of them. A dainty meal, choice wines, slippers, clean linen—in short, everything necessary or agreeable to a weary traveller were collected together, that he might want for nothing, and that the delights of home might remind him of a mother's love.

The Countess went and placed a seat at the table, as if to realize her prayers and increase the strength of her illusions. As she did so she cried, in a heart-rending voice, "Brigitte!"

"Ah, Madame, he *will* come; he cannot be far off. I am certain that he is alive and on the way," replied Brigitte. "I put a key in the Bible, and rested it on my fingers, while Cottin read the Gospel of St. John—and, Madame, the key did not turn."

"Is that a sure sign?" asked the Countess.

"Oh, Madame, it's well known; I would stake my soul that he is alive. God would never deceive us like that."

"In spite of the danger he will be in here! Still I long to see him."

"Poor Monsieur Auguste!" cried Brigitte, "no doubt he is on the roads, on foot."

"Hark! that is eight striking," exclaimed the Countess in terror.

She was afraid that she had stayed too long in the room, but there she could believe that her son still lived when she saw everything bear witness to his life. She went down-stairs, but before going into the salon she waited a moment under the colonnade of the staircase, and listened for some sound to awaken the silent echoes of the town. She smiled at Brigitte's husband, who kept watch like a sentinal; his eyes seemed stupefied with straining to catch the murmurs of the *Place* and the first sounds of the night. Everywhere and in everything she saw her son.

A moment afterwards she had returned to her guests affecting an air of gaiety, and sat down to play at loto with some girls. But every now and then she complained of feeling unwell, and went to recline in her easy-chair by the fireplace.

Such was the situation, material and mental, in the house of Madame de Dey. Meanwhile, on the high road from Paris to Cherbourg, a young man clad in a brown carmagnole, a costume in vogue at this period, directed his steps towards Carentan.

In the commencement of the *Requisitions* there was little or no discipline. The exigencies of the moment scarcely allowed the Republic to equip its soldiers fully at once, so that it was nothing unusual to see the roads full of *requisitionnaires* still wearing their civil clothes. These young men arrived at the halting-places before their battalions, or remained there behind them, for the progress of each man depended on his personal capability of enduring the fatigues of a long journey. The traveller in question found himself considerably in advance of a battalion of *requisitionnaires* which was on its way to Cherbourg, and which the Mayor of Carentan was waiting for from hour to hour, to billet on the inhabitants. The young man walked with heavy steps, but still he did not falter, and his gait seemed to show that he had long been accustomed to the severities of military life. Though the moon shed her light upon the pastures arouud Carentan, he had noticed a thick white bank of clouds ready to cover the whole country with snow. The fear of being caught in a hurricane no doubt hastened his steps, for he was walking at a pace little suited to his weariness. He carried an almost empty knapsack on his back, and in his hand a box-wood stick, cut from one of the high thick hedges which this shrub forms round most of the estates of Lower Normandy.

The towers of Carentan, thrown into fantastic relief by the moonlight, had only just come into sight when this solitary traveller entered the town. His footfall awakened the echoes of the silent streets. He did not meet a creature, so he was obliged to inquire for the house of the Mayor from a weaver who was still at work. The Mayor lived only a short distance off, and the *requisitionnaire* soon found himself under shelter in the porch of his house. Here he applied for a billet order and sat down on a stone seat to wait. However, the Mayor sent for him, so he was obliged to appear before him and become the object of a scrupulous examination. The *requisitionnaire* was a foot soldier, a young man of fine bearing, apparently belonging to a family of distinction. His manners had the air of gentle birth, and his face expressed all the intelligence due to a good education.

"What is your name?" asked the Mayor, casting a knowing glance at him.

"Julien Jussieu," replied the *requisitionnaire*.

The magistrate let an incredulous smile escape him. "And you come—"

"From Paris."

"Your comrades must be some distance off," replied the Norman in a bantering tone.

"I am three leagues in front of the battalion."

"No doubt some sentiment draws you to Carentan, *citoyen requisitionnaire?*" said the Mayor with a shrewd look. "It is all right," he continued. The young man was about to speak, but he motioned him to be silent and went on, "You can go, *Citoyen Jussieu!*"

There was a tinge of irony discernible in his accent, as he pronounced these two last words and held out to him a billet order which directed him to the house of Madame de Dey. The young man read the address with an air of curiosity.

"He knows well enough that he hasn't got far to go; when he's once outside he won't be long crossing the *Place!*" exclaimed the Mayor, talking to himself as the young man went out, "He's a fine bold fellow; God help him! He's got an answer ready to everything. Ay, but if it had been any one else but me, and they had demanded to see his papers,—it would have been all up with him."

At this moment the clocks of Carentan struck half-past nine. In the ante-chamber at Madame de Dey's the lanterns were lighted, the servants were helping

their masters and mistresses to put on their clogs and *houppelandes* and mantles, the card players had settled their accounts, and they were all leaving together, according to the established custom in little towns.

When they had exhausted all the formularies of adieu and were separating in the *Place*, each in the direction of his own home, one of the ladies observing that that important personage was not with them, remarked, "It appears that the Prosecutor intends to remain."

As a matter of fact, the Countess was at that moment alone with that terrible magistrate; she waited, trembling, till it should please him to depart.

After a long silence, which inspired her with a feeling of terror, he said at last, "*Citoyenne*, I am here to carry out the laws of the Republic."

Madame de Dey shuddered.

"Hast thou nothing to reveal to me?" he asked.

"Nothing," she replied, in astonishment.

"Ah, Madame," cried the Prosecutor, sitting down beside her and changing his tone, "at this moment one word could send us—you and me—to the scaffold. I have watched your character, your mind, your manners too closely to share in the mystification by which you have succeeded in misleading your guests this evening. You are expecting your son, I have not the least doubt of it."

The Countess made an involuntary gesture of denial; but she had grown pale, the muscles of her face had contracted under the necessity of displaying a coolness she did not feel; the pitiless eye of the Prosecutor had not lost one of these movements.

"Well! receive him," replied this magistrate of the revolution, "but do not let him remain under your roof after seven o'clock in the morning. To-morrow at daybreak I shall come to your house armed with a denunciation which I shall get drawn up."

She looked at him with a bewildered, numbed look that might have drawn pity from a tiger.

"I shall demonstrate," he continued sweetly, "the falsity of this denunciation by a careful search. You will then be screened by the nature of my report from all ulterior suspicions. I shall speak of your patriotic gifts, your *civism*, and we shall be saved."

Madame de Dey suspected a snare; she remained motionless, her tongue was frozen and her face on fire. The sound of the knocker echoed through the house.

"Ah," cried the mother as she fell in terror upon her knees, "save him! save him!"

The Public Prosecutor cast a passionate glance at her.

"Yes, let us save him," he replied, "even at the cost of our own lives." He raised her politely.

"I am lost," she cried.

"Ah, Madame!" he answered, with an oratorical gesture, "I would not owe you to anything—but to yourself alone."

"Madame, he's——" cried Brigitte, thinking her mistress was alone.

At the sight of the Public Prosecutor, the old servant, who had burst in, beaming with joy, grew pale and motionless.

"Who is it, Brigitte?" asked the magistrate, with an air of gentle intelligence.

"A *requisitionnaire* sent us from the Mayor's to lodge," answered the servant, showing him the billet order. The Prosecutor read the paper. "True," said he; "a battalion is coming to us to-night." He went out.

At that moment the Countess had too much need to believe in the sincerity of her former attorney for the least doubt of it to cross her mind!

Though she had scarcely the power to stand, she ascended the staircase precipitately, opened the door of the room, saw her son, and threw herself half dead into his arms. "My child, my child," she sobbed, almost beside herself, as she covered him with kisses.

"Madame!" said a stranger's voice.

"Ah, it is not he!" she cried, recoiling in horror, She stood upright before the *requisitionnaire* and gazed at him with haggard eyes. "My good God, how like he is!" said Brigitte. There was a moment's silence; even the stranger shuddered at the sight of Madame de Dey.

The first blow had almost killed her, and now she felt the full extent of her grief. She leant for support on Brigitte's husband. "Ah, Monsieur, she said, "I could not bear to see you any longer. Allow me to leave you for my servants to entertain."

She went down to her own room, half carried by Brigitte and her old manservant. "What! Madame," cried the housekeeper, as she led her mistress to a chair; "is that man going to sleep in Monsieur Auguste's bed, and wear Monsieur Auguste's slippers and eat the pastry that I made for Monsieur Auguste? If I was to be guillotined for it, I——"

"Brigitte!" cried Madame de Dey.

Brigitte was mute.

"Hold thy tongue, chatterbox," said her husband in a low voice. "Dost want to kill Madame?"

At this moment the *Requisitionnaire* made a noise in his room as he sat down to the table.

"I cannot stay here," cried Madame de Dey. "I will go into the conservatory; I shall be able to hear better there what goes on outside during the night."

She was still tossed between the fear of having lost her son and the hope of seeing him come back to her.

The silence of the night was horrible. The arrival of the battalion of *Requisitionnaires* in the town, when each man sought his lodging, was a terrible moment for the Countess. Her hopes were cheated at every footfall, at every sound; presently nature resumed her awful calm.

Towards morning the Countess was obliged to return to her own room.

Brigitte, who was watching her mistress's movements, not seeing her come out, went into the room and found the Countess dead.

"She must have heard that *Requisitionnaire*," cried Brigitte. "As soon as he has finished dressing, there he is, marching up and down Monsieur Auguste's bedroom, as if he were in a stable, singing their damned *Marseillaise!* It was enough to kill her."

The death of the Countess was due to a deeper sentiment, and doubtless caused by some terrible vision. At the exact hour when Madame de Dey died at Carentan, her son was shot in le Morbihan.

We may add this tragic event to all the evidence of sympathies ignoring the laws of space, which has been collected through the learning and curiosity of certain recluses. These documents will some day serve as the groundwork whereon to base a new science—a science which has hitherto lacked its man of genius.

HOW IT GOT INTO PRINT.

A Story of a Canadian Village.

Walter Blackburn Hart in the *Boston Transcript*.

A stranger in St. Barthelemi chancing to saunter into the Revere House, and hearing old Peter Runians, the proprietor of the hotel, bawling out at the top of his cheery stentorian voice for "Topsy," might very naturally expect to catch the rustle of starched feminine petticoats on the winding staircase, or in the narrow hallway leading to the public dining-room and the region of pots and pans, followed by the appearance of a stout, red-cheeked Canadian lass.

But "Topsy" was a boy.

Everybody in St. Barthelemi knew "Topsy;" indeed, his fame was not confined within the narrow limits of his native village. "Topsy" of St. Barthelemi was a familiar character in almost every inn parlor in the villages and towns along the St. Lawrence up to Montreal. In the roar of the great city "Topsy" lost his identity—which was only to be expected—though Peter Runians, in his infrequent visits to the city, found the fact very hard to understand. But the regular boarders, and those guests who had experienced the old-fashioned hospitality of the Revere House on previous occasions, all knew whom to expect in answer to the loud, imperative summons that rang through the house so often. Old Runians never seemed happy unless the boy was about him.

An almost involuntary lull took place in the conversation of the bar-room whenever "Topsy" was called, and the loungers listened for the quick patter of his little iron-tipped crutch, as the boy hurried responsive to the call. When he was a little fellow of five years old, "Topsy" had lost his left leg from the knee down through an accident with a mowing machine at harvest time, but he managed to fly along with his crutch like a whirlwind. All had learned to love and pity the poor little cripple, and his quickness of parts had won for him a reputation as an intellectual prodigy. Old Peter Runians used to roar out "Topsy! Topsy!" like a devouring lion; but the gruffness of his voice was merely a kind of occult humor, startling enough to strangers, but quite transparent to the boy and all the regular customers of the place. The old lion used to smile as he roared; and often, as he bent over the unabashed "Topsy," with his heavy brows knit sternly, he would roll out, "You darned little scoundrel, yer, what 'ev you bin doin'?" and then suddenly lifting the boy off his feet, he would shake him in the air as fondly and tenderly as a mother does her babe.
